Cleveland

The purpose of this report is to direct attention to lithium intoxication as a complication of the use of lithium chloride as a salt substitute for flavoring low sodium diets. We shall describe the syndrome as it was observed in 7 cases, in 2 of which the intoxication seems to have been a contributory cause of death. The salt substitute used by these patients was westsal,® which is a solution of lithium chloride with citric acid and a small amount of potassium iodide. That the cause of the intoxication was lithium ion, and not sodium depletion as such, seems evident from a study of these cases, in 1 of which the intoxication was induced as a clinical trial. Nevertheless, the data indicate that sodium depletion, incident to treatment with low sodium diets, increases the susceptibility to intoxication from orally ingested lithium salts.

The suspicion that lithium might be the cause of poisoning in patients deprived of dietary sodium was aroused by events in the first patient to be described. However, in this case, as in the second, the diagnosis is retrospective and presumptive and based on the sequences in the third and succeeding patients observed.

REPORTS OF CASES

Case 1.—The patient was a 70 year old white woman whose primary disease was generalized arteriosclerosis with severe arteriosclerotic heart disease and congestive heart failure. In December 1947 she was placed on a diet containing about 200 mg. of sodium per day. A salt substitute in powder form, consisting principally of potassium and lithium chlorides, was used for flavoring until May 1948, when westsal® was substituted for it. No untoward symptoms appeared until the first week in August 1948, during a hot spell. On August 5 about 20 cc. of the salt substitute was used in the preparation of a stew, which the patient ate with enjoyment. She was seized with giddiness and nausea on the next day and, during the following twenty-four hours, showed mental confusion, apathy and gross tremor of the arms and legs. The deep reflexes were hyperactive. She was admitted to hospital August 7, and became comatose on August 8, with spontaneous gross tremor of the chin, lips, eyelids, arms and leg muscles. Clonus was initiated by tendon tapping. A grasp reflex was present bilaterally. Abdominal reflexes were absent. Hoffman, Gordon and Oppenheimer signs were strongly positive. The Babinski test yielded plantar flexion. Lumbar puncture gave fluid of normal composition, under normal pressure and with normal dynamics.

A neurologic consultant noted, "I have never seen such striking muscular irritability in a cerebral lesion. Strychnine poisoning, tetanus and tetany should be considered." An electroencephalogram on August 9 showed a severe generalized slow dysrhythmia with frequencies of 4 to 6 per second and voltages up to 150 millivolts. A neurologic consultant suggested that such an electroencephalogram and clinical state might result from multiple small cerebral emboli. Treatment meanwhile had been supportive, with phenobarbital for restlessness and fluid balance maintained with intravenous fluids (10 per cent dextrose in water and 5 per cent dextrose in 1 per cent solution of sodium chloride). Serum chloride content was 104 milliequivalents per liter and carbon dioxide–combining power 49 volumes per cent on August 9. Serum potassium at the time was 3 milliequivalents per liter.

By August 11 she had cleared mentally and was taking fluid by mouth; in succeeding days she improved rapidly, and was discharged in good condition on August 14, having at that time amnesia for the week of her illness. She continued well during the next ten days, and resumed her former diet and use of westsal.® Again tremor, confusion and apathy developed; she passed into coma and died on Aug. 27, 1948. An autopsy was not obtained.

Summary.—In an elderly woman under treatment for congestive heart failure which included the use of westsal® and of a low sodium diet, twice during hot summer a syndrome of tremor, muscular and reflex hyperirritability, confusion and coma developed. An electroencephalographic abnormality was demonstrated. The serum potassium was abnormally low. The patient died during the second episode. The diagnosis of lithium intoxication, suspected then by one of us, has been established by the observations in the succeeding cases.

Case 2.—This patient, a 66 year old woman suffering from generalized arteriosclerosis, arteriosclerotic heart disease, osteoarthritis, an anxiety state and an infection of the urinary tract, was not observed during life by any of us. The course of events is therefore summarized from clinical notes in her chart and from the statement of her special nurse. On admission to hospital, Sept. 18, 1948, she was placed on a low sodium diet, and, because she complained of the lack of flavor, was given westsal® on the following day. The notes indicate that she was mentally confused on September 26. The nurse states that she asked for a special nurse because of the patient's confusion and bizarre appearance, blurring of vision, instability in walking and a tremor of the arms which made it difficult to feed herself or to achieve a legible signature, although her appetite was maintained and she is stated to have "bathed" her food in the salt substitute. On October 1 she was unable to walk, even when assisted, and had to be fed. On October 2 she complained of paralysis of the right hand and showed mental lapses, confusion and disorientation. The nurse, thinking that she was overdosing herself with barbiturates, locked her supply away. On October 4 her blood pressure had fallen from the admission level of 170 mm. of mercury systolic and 84 diastolic to 154 systolic and 40 diastolic; on October 5 it was recorded as 70 systolic and 30 diastolic. By that time she was taking fluids only and had passed into a coma from which she was infre-

---

From the Research Division and the Frank E. Bunts Institute, Cleveland Clinic Foundation.

quently roused. She showed muscular irritability on being moved and spontaneous tremor. No pathologic reflexes were elicited. The impression was that she had multiple small cerebral emboli or thromboses. She continued in coma with episodes of Cheyne-Stokes respirations and evidences of neuromuscular hyperirritability until death on October 12. She had been sustained between October 7 and 12 on occasional infusions of 5 per cent dextrose, and her restless delirium treated with chloral hydrate and paraldehyde. An autopsy was not performed.

Summary.—A retrospective diagnosis of lithium intoxication is made in the case of an arteriosclerotic patient on a low sodium diet who took an excessive quantity of westsal® for flavoring her food. The course was marked by tremor, mental lapses and terminal coma.

Case 3.—The patient is a Negro man, 47 years of age, whose primary disease is severe essential hypertension. On July 26, 1948, he was placed on a diet containing about 200 mg. sodium daily and began the use of westsal® as a salt substitute, in cooking and on food. For the first four weeks of this regimen, he was given 6 Gm. sodium chloride daily in enteric-coated capsules as a control observation on the effects of low sodium diet. This supplement was withdrawn August 24. He was unable to maintain the desired degree of sodium restriction for the next four weeks. On October 4 he complained of occasional "nervous twitches," which subsided during the following week. He was again unable to maintain his dietary regimen, and the apparent urinary sodium contents varied from 0.6 to 2.2 Gm. per 24 hours. On November 8 he was emphatically counselled to improve his dietary control. He promised to cooperate and, on November 22, apparent urinary sodium was 0.94 Gm. However, he complained that he was able to sleep only for short periods at a time because of muscle twitches and "nervousness." These complaints were not relieved by oral administration of seconal sodium® (sodium 5-allyl-5-[1-methylbutyl] barbiturate), 0.1 Gm., at bed time. Rather, on November 29, gross tremor of his hands and arms developed which was obvious to the members of his family. He was unable to sleep and was despondent, causing his wife concern over his mental status. During the whole period from July he had maintained a steady rate of use of westsal,® averaging 2 two and one-fourth ounce bottles monthly. Apparent urinary sodium was 0.7 Gm. per 24 hours. December 2 he was advised to discontinue westsal® and otherwise to maintain his regimen as before. His symptoms of tremor, apathy and twitching diminished during the next two days and had disappeared when he was seen on December 6. At this time the urinary sodium output was estimated as 0.23 Gm. per 24 hours. This level of urinary sodium output was maintained during the next six weeks. None of the symptoms has returned.

Summary.—A patient suffering from essential hypertension was placed on a low sodium diet supplemented with westsal® and, for the first four weeks, with sodium chloride. Muscle twitches appeared transiently during a period of unsteady dietary control. These, together with insomnia, depression, apathy and fatigue, reappeared three weeks after he had agreed to maintain a severe sodium restriction. These symptoms disappeared four days after discontinuing the use of westsal,® although sodium restriction was continued. It is deemed significant that, with a steady rate of ingestion of lithium chloride, symptoms appeared and progressed only during rigid sodium restriction, although muscle twitches had occurred transiently before.

Urinary sodium was measured colorimetrically from the precipitate obtained with uranyl zinc acetate (Hoffman and Osgood[1]), a reagent which can also be used in the determination of lithium (Woodfin[2]). The drop in apparent urinary sodium content from levels of 0.9 and 0.7 Gm. while using lithium chloride as a salt substitute to levels of about 0.25 Gm. after discontinuing it reflects inclusion of urinary lithium in the analyses for sodium.

The course of events indicated that the use of westsal® as a salt substitute causes toxic symptoms during periods of severe sodium restriction and thus gave grounds for tentative retrospective diagnoses in the first and second patients reported.

Case 4.—A white man, 35 years of age, was admitted suffering from chronic glomerulonephritis with early renal failure (blood urea, 96 mg. per hundred cubic centimeters) Dec. 21, 1948. He had been placed on a low sodium diet containing about 0.5 Gm. sodium on October 8, which he supplemented with westsal® as a flavoring agent. On admission, together with evidences of his primary disease he showed a coarse tremor of the arms which interfered with his feeding himself and complained of blurring of vision. Both symptoms had been present since the end of October. His deep reflexes were hyperactive. Lithium intoxication was suspected and westsal® discontinued. He was given infusions of 5 per cent dextrose in water daily for the next week, at the end of which his blood urea content was unchanged, while his symptoms and reflex hyperexcitability had disappeared. At this time administration of 3 Gm. lithium chloride in 24 hours did not cause the symptoms to recur.

Case 5.—A 51 year old Negro woman suffering from congestive heart failure due to arteriosclerotic heart disease, with other diagnoses of diabetes mellitus, intercapillary glomerulosclerosis and obesity, was admitted to the hospital Jan. 5, 1949. She was placed on a diet estimated to contain 0.5 Gm. sodium daily and given westsal® as a salt substitute. She was also treated with digitalis and mercurial diuretics. On this regimen she lost 16 pounds (7.3 Kg.) in weight in the first week. Discharge from hospital was planned for January 14, on which day twitching of the left hand developed, and by evening she had become mentally confused without specific neurologic signs. On January 15 she was in restless coma. The plasma carbon dioxide-combining power was 48 volumes per hundred cubic centimeters and the serum chloride 93 milliequivalents per liter. She remained comatose and had to be restrained on January 16 and 17, showing also generalized muscular twitching and hyperactive tendon reflexes. The blood urea rose to 140 mg. per hundred cubic centimeters from a level of 60 mg. on admission, an increase in azotemia which was attributed to dehydration. At this time serum chloride was 113 milliequivalents per liter and carbon dioxide-combining power 40.4 volumes per hundred cubic centimeters. When she was seen by one of us on January 20, it was advised that she be given sufficient fluid to maintain a urine output of at least 2 liters daily and that this regimen should include administration of 5 Gm. sodium chloride daily. She was conscious and much improved on January 23 and was discharged from hospital on January 29 with all evidences of the intoxication relieved.

Summary.—In patients 4 and 5, sodium restriction was not as severe as in the others of this series. However, in both there were evidences of impaired renal function and, in patient 5, a negative sodium balance was created by the use of mercurial diuretics. In patient 4, evidences of toxicity from the use of lithium appeared in about three weeks and stabilized at a level of minor annoyance. In patient 5 the intoxication developed suddenly and was very severe. Its greater severity in patient 5 is attributable to the sodium depletion which had been created in this case.

Case 6.—The patient is a 42 year old white man suffering from severe essential hypertension, for which he was placed on a low sodium diet (200 mg. estimated daily sodium content)

[2] Woodfin, W. C.: The Determination of Lithium, J. A. Off. Agric. Chem. **30**: 482, 1947.

Jan. 29, 1949, and given westsal® as a salt substitute. During the next ten days he consumed the equivalent of about 8.5 Gm. of lithium chloride. On the fifth day he had difficulty in thinking clearly, on the eighth day he staggered slightly on walking and on the night of the tenth day was twice wakened from sleep by atacks of muscle twitching. On examination on the eleventh day he showed coarse tremor of the hands (record *D* in fig. 1) with hyperactive deep reflexes and hyperirritability of facial muscles. Westsal® was discontinued and he was told to take as much sodium chloride as would flavor his food. His symptoms diminished greatly during the next three days, as evidenced by decrease of tremor (record *E* of the figure) and had entirely receded at the end of one week.

Case 7.—The patient is a Negro man, 46 years of age, who suffers from severe essential hypertension and advanced retinal and cerebral arteriosclerosis. After prolonged observation in hospital he was placed on a rice diet (Kempner) on Dec. 8, 1948.

A technical complication of treatment with low sodium diets is shown by the fact that during the next five weeks this patient's urinary sodium averaged about 0.6 Gm. per 24 hours. The source of the extra sodium was found to be a proprietary laxative (mucara®) which he had been taking. When this was withdrawn, urinary sodium levels fell to reach a low of 0.05 Gm. per 24 hours on Jan. 25, 1949.

As a clinical test of the possibility of intoxication with lithium from westsal,® he was given the salt substitute to use on his food on January 28. His plasma carbon dioxide-combining power was 57 volumes per cent and serum chloride 88 milliequivalents per liter at this time. Three days later he complained of weakness and fatigue and showed muscle twitches and tremor of the hands. The total amount of lithium chloride ingested by the fourth day was 4.8 Gm. On this day he walked with a staggering gait, the Romberg sign was positive, the deep reflexes were hyperactive and there was fasciculation of muscles at the site of percussion. He showed a coarse tremor of the arms, even at rest, and spontaneous twitchings of leg muscles. On the fifth day he complained of retarded mentation, loss of memory and uneasy somnolence. All these symptoms and signs increased during the next two days, so that he was prostrate, depressed and confused and unable to walk without assistance. From the fourth to the seventh day inclusive he took only 0.4 Gm. of lithium chloride, so that the total dose in the seven days was 5.2 Gm., when its administration was stopped.

Current in Milliamperes Required for Stimulation of Muscles in Successive Observations on Patient 7

GALVANIC STIMULATION

	Dates			
Muscles	2-3	2-5	2-9	2-15
Right biceps	2	2	4	7
Right flexor ulnaris	1	1	2	6
Right gastrocnemius	7	4	6	5
Left biceps	1	1	2	5
Left flexor ulnaris	2.5	2	4	2
Left gastrocnemius	4	3	8	7

Evidences of intoxication continued unabated on the eighth and ninth days of the test. His condition caused concern, so that on the ninth day he was given intravenously an infusion of 1 liter of 5 per cent dextrose in 1 per cent solution of sodium chloride. On the next day he was mentally clearer, although tremors and hyperactive reflexes were unchanged. Tremor decreased on the eleventh day. On the twelfth day he was able to walk unassisted and showed only minor tremor and reflex hyperactivity. All evidences of intoxication vanished on the eighteenth day after administration of westsal® was begun, which was the eleventh day after it had last been taken.

As objective estimates of the course of the intoxication, neuromuscular functions were tested in three ways. The first test, a record of tremor, is illustrated in figure 1 (tracings *A* and *B*) done respectively on the sixth and the thirteenth day of this observation. The severity of tremor was such that the recorder of vertical movement had to be disconnected in the tracing done February 3. The improvement in tremor is obvious, but its persistence can be seen by comparison of the record of February 12 with the record of a normal person (fig. 1 *C*).

The second estimate was from the galvanic excitability of muscles. This measurement was supplied us by Dr. Shelby G. Gamble. The results of his observations are tabulated (the table).

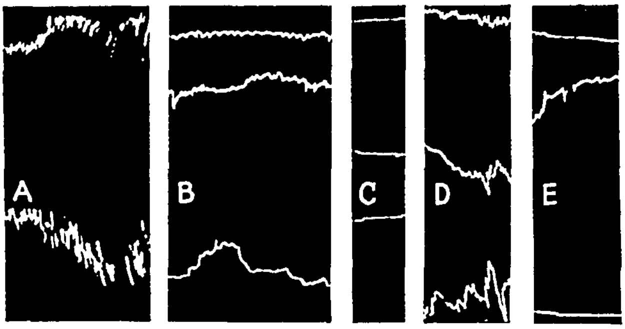

Fig. 1.—Kymograms of finger tremor. Records *A* and *B* were made by patient 7, respectively on Feb. 3 and 10, 1949. Record *C* is that of a normal person. Records *D* and *E* were made by patient 6, respectively on Feb. 9 and 12, 1949.

The third objective estimate was from the electromyographic records (Dr. Edward Zucker) (fig. 2) obtained on the seventh and thirteenth days of intoxication.

COMMENT

In 1913 Dr. S. A. Cleaveland of this city described in The Journal [3] an experiment in lithium intoxication which he performed on himself. He ingested 2 Gm. of lithium chloride after each meal for three meals and one more dose at bedtime, totaling 8 Gm. in the eighteen hours. Three to four hours after the first dose he felt dizziness and fulness of the head. The third dose was followed by blurring of vision, dizziness and tinnitus, generalized weakness and marked tremor. After the fourth dose, dizziness increased and caused sleeplessness. His symptoms persisted so that he remained in bed the next day. Muscular weakness and tremor persisted for five days. He repeated the experiment some months later, when he took 4 Gm. of lithium chloride and experienced dizziness, tinnitus and blurring of vision.

The symptoms presented by our patients are, in order of appearance, tremor, muscle twitches, apathy, difficult mentation, blurring of vision, confusion and, finally, coma and death. Objective evidences are reflex hyperirritability, muscle fasciculation and hyperirritability of muscles to galvanic stimulation. These toxic manifestations are not dissimilar from those experi-

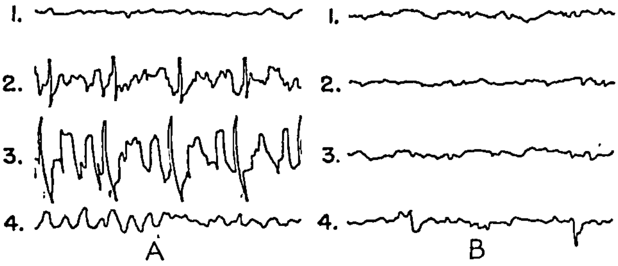

Fig. 2.—Electromyograms (patient 7). *A*, records of Feb. 7, 1949. Muscles tested from above down are (1) left thigh, (2) right anterior tibial, (3) right triceps and (4) left biceps. *B*, records of Feb. 12, 1949. Muscles from above down are left thigh, right anterior tibial, left biceps and right triceps.

[3] Cleaveland, S. A.: A Case of Poisoning by Lithium, Presenting Some New Features, J. A. M. A. **60**: 722 (March 8) 1913.

enced by Dr. Cleaveland and lead to the conclusion that the intoxication in our patients is due to the action of lithium.

It is noteworthy that in our patients evidences of intoxication appeared on dosages of lithium chloride much less than the dose taken by Dr. Cleaveland in the course of one day. It is therefore likely that sodium restriction increases susceptibility to the toxic action of lithium. This can be attributed to replacement of some of the sodium ions missing from body fluids by lithium. We are not aware of any complete explanation of the metabolic disturbances induced in muscles and nerves by substitution of lithium for sodium, although Runnström[4] has demonstrated the toxic effects of lithium on the development of sea urchin eggs. In normal persons lithium ion is readily absorbed and readily excreted, largely in the urine.[5] The slow recovery from intoxication in patient 7 of our series until sodium was given is further evidence for ionic competition between sodium and lithium and suggests that the treatment of severe lithium poisoning is best accomplished by liberal provision of sodium ion and of water.

SUMMARY

It is evident that the use of salt substitutes as flavoring agents for low sodium diets should not go unsupervised. Some of them contain potassium, which may be toxic to patients with renal insufficiency (Keith and Burchell[6]), as are many patients given the rice diet. The salt substitute, westsal,® which appears to be responsible for toxicity in our patients consists substantially of lithium chloride. Patients on low sodium diets exhibit an increased susceptibility to the toxic effects of lithium, as shown in patient 7, who had severe symptoms from a total dose of only 5.2 Gm. of lithium chloride. In 1 patient, the equivalent of about 4 Gm. of the salt resulted in an illness which, from the descriptions given, was no more severe than the illness from which she died. It is, perhaps, significant that the patients who showed severe manifestations (patients 1, 2, 7) suffered clinically from advanced cerebral arteriosclerosis.

ADDENDUM

G. MASSON, PH.D.

As one of a series of pharmacologic tests of the toxicity of lithium chloride, the effect of sodium restriction and of sodium supplements was examined in rats. The animals averaged 200 Gm. body weight. Two groups of 10 animals each were tested. One group was placed on a low sodium diet consisting of starch, dextrin and casein for three days before beginning the experiment. The other group was on a diet of fox chow and was given 1 per cent sodium chloride solution as drinking water. On the third and succeeding days of the experiment, both groups received by gavage 50 mg. of lithium chloride in 10 cc. of water. In the case of the sodium-containing diet group, 100 mg. of sodium chloride was added to the lithium chloride solution given by gavage.

Animals given lithium chloride only and deprived of sodium lost appetite during the first twenty-four hours and showed roughening of their fur. By the third day of treatment with lithium chloride, 3 animals had died in this group, and all but 1 had died by the end of the fourth day. Before dying, these animals became irritable and showed diffuse muscle tremors spontaneously and on stimulation.

In contrast, rats given the sodium chloride supplements remained in good condition.

The data, which fit in well with the clinical studies reported, indicate toxicity of lithium chloride in rats given low sodium diets and a definite protection against lithium by the provision of supplementary sodium.

LITHIUM CHLORIDE AS A SUBSTITUTE FOR SODIUM CHLORIDE IN THE DIET

Observations on Its Toxicity

LAWRENCE W. HANLON, M.D.

FRANK J. GILROY, M.D.
New York
and
JOHN E. DEITRICK, M.D.
Chicago

In view of the increasing emphasis on restriction of sodium intake in the management of cardiac decompensation and other conditions, a harmless substitute for salt in the seasoning of food has been widely sought and is much to be desired. Recently a 25 per cent solution of lithium chloride, which has a taste similar to table salt, has been made commercially available. Although there are in the older literature scattered records suggesting that ingestion of inorganic lithium salts may cause weakness, tremors and blurring of vision, the solution has been marketed with the assurance of the distributors that it is "perfectly safe," but they recommend that it be used only under the supervision of a physician. Our acquaintance with lithium began in the last two months of 1948, when we undertook the study of the absorption, distribution and excretion of lithium chloride as part of a long range investigation of electrolyte patterns in patients under treatment for heart failure. In the preliminary phase of the work the possibility of serious toxicity from the drug was brought to our attention by the cases presented in this report.

REPORTS OF CASES

Case 1.—The patient, C. D., was a 58 year old white man, a rock driller for thirty years, who had arteriosclerotic heart disease and pulmonary emphysema and fibrosis. He was first treated for cardiac decompensation in 1944 and from June until September 1948 was observed at Bellevue Hospital during a recurrence of heart failure. A month at home with digitalis, low salt diet and mercurial diuretics ended in severe failure that required his readmission in October. At that time examination revealed pronounced cardiac enlargement, rales in both lungs, a greatly enlarged liver and extensive peripheral edema. No abnormal neurologic signs were discovered. The venous pressure was 180 mm. of saline solution and sodium dehydrocholate circulation time was 36 seconds. The blood urea nitrogen was 53 mg. per hundred cubic centimeters and the total serum protein was 6.9 Gm. per hundred cubic centimeters.

The patient was placed on a management consisting of bed rest, low salt diet and meralluride (mercuhydrin®) 2 cc. intramuscularly daily. Because of coupled rhythm digitalis was discontinued until the seventh hospital day. On the fifth day

Research fellow, The National Institute of Health, United States Public Health Service, Bethesda, Md. (Dr. Hanlon).

This study was supported by a grant from the National Institute of Health, United States Public Health Service, Bethesda, Md.

of observation quinidine sulfate, 0.2 Gm. every six hours, was started and two days later the premature contractions had disappeared. There was, however, no improvement in the signs or symptoms of failure.

On the tenth hospital day he was given a rice diet and daily mercurial diuretics were continued. After twenty-six days on this regimen he had lost 53 pounds (24 Kg.) and felt markedly improved. Signs of cardiac failure had disappeared, the venous pressure and circulation time were within normal limits and the blood urea nitrogen had fallen to 19 mg. per hundred cubic centimeters. Mercurial diuretics were discontinued on the thirty-seventh hospital day.

On the fifty-first hospital day the patient was given lithium chloride and instructed to season his food with it. He found this substance a pleasant substitute for salt and used it liberally. In about three days he had ingested approximately 13 Gm. On the morning of the third day after lithium was begun he complained of generalized weakness but no other symptoms. The following morning the weakness had increased so that he was unable to hold his eating utensils. He complained that his head was "reeling," and a coarse tremor was present on extension of his hands. He was anorexic and nauseated, but did not vomit. Lithium was discontinued. During that day the weakness increased and he slept excessively. Deep tendon reflexes had become slightly hyperactive, but no other pathologic reflexes were present.

* Lithium was determined with a Perkin-Elmer Flame Photometer, Model 52A. Normal blood plasma in a 1:10 dilution causes a meter deflection on this machine equivalent to as high as 0.5 milliequivalent per liter of lithium. This may be due in part to interference from sodium and potassium.

† Part of the urine for this day was measured and discarded through error before electrolyte concentrations were determined. In the urine excreted subsequently the concentrations were approximately the same as on the previous day.

On the next day (five days after starting and one day after discontinuing lithium) the symptoms were worse. He was extremely lethargic and slept continuously, but could be aroused. His pulse was 78 and regular, his blood pressure was 136 systolic and 66 diastolic. Muscular weakness was generalized; the muscles of the extremities were flaccid at rest. A coarse tremor was present on movement and there were spontaneous fascicular twitchings and spasms of clonic contractions of large muscle groups of the trunk and all extremities. The deep tendon reflexes remained hyperactive. An electrocardiogram revealed no significant change from a series of previous records.

Six days after lithium was begun and two days after it had been stopped he had become confused and disoriented. There was a continuous, coarse, nonrhythmic and nonoscillating tremor of all the extremities. The deep tendon reflexes were unchanged, but gentle tapping of any muscle caused a clonic contraction of the associated muscle group. The plantar responses were normal. The pulse was 136 and regular and the blood pressure was 156 systolic and 100 diastolic. Throughout the day he had drenching sweats. At noon he was given 450 cc. of 5 per cent dextrose in isotonic sodium chloride solution because the plasma sodium level was low. The infusion was discontinued because pulmonary edema began to develop. He was given mercurophylline 1 cc. intravenously, and in several hours the pulmonary edema had cleared appreciably. Thereafter, a slow infusion of 2,000 cc. of 5 per cent dextrose in water was well tolerated. Later in the day he became comatose. An electrocardiogram revealed intraventricular heart block which disappeared several hours later.

The following day (seven days after lithium was begun and three days after it was discontinued), the patient remained comatose. His temperature was 102 F., his blood pressure had fallen to 70 systolic and 50 diastolic, and his pulse was 108 and regular. Respirations were deep and regular, 28 per minute. The tremor had decreased. The skin was moist and warm. Because the carbon dioxide–combining power had been falling steadily he was given 275 cc. of 1.7 per cent sodium bicarbonate solution and 3,000 cc. of 5 per cent dextrose in water intravenously. No significant change was noted in his clinical condition. The following morning tracheal rales developed, and he died shortly thereafter. Permission for autopsy was not granted.

The results of the study of electrolytes in this patient during the period of lithium administration are shown in table 1.

The patient received approximately 13.0 Gm. of lithium chloride in seventy-two hours. The highest blood level of lithium was 4.8 milliequivalents per liter on the day lithium chloride was discontinued. Three days later, one day prior to death, the blood level was 3.0 milliequivalents per liter. A total of 4.15 Gm., approximately 40 per cent of the lithium chloride administered, was recovered in the urine, including that excreted for two days after the last dose.

We are of the opinion that the toxic effects of the excessive amount of lithium chloride ingested by the patient contributed to, if they did not actually cause, his death. Although he was already ill with a serious cardiac disease, his rapid downhill course began after the administration of lithium chloride and the only new symptoms were similar to those attributed in other patients to lithium toxicity. When he became comatose and was unable to take fluids by mouth his low cardiac reserve and tendency to pulmonary edema interfered with appropriate treatment.

This patient presented the first indication of dangerous toxicity. We had, however, suspected some toxic action from our experiences in cases 2 and 3. Case 4 was brought to our attention by one of the visiting physicians.

CASE 2.—A. C., a 60 year old white man, a chronic alcoholic addict, was admitted to Bellevue Hospital in August 1948 because of swelling of the abdomen, peripheral edema and exertional dyspnea of three weeks' duration. Physical findings and the results of laboratory investigation were consistent with a diagnosis of cirrhosis of the liver. During his first forty-three hospital days he received a regular ward diet without added salt and with vitamin supplements. From the second to the fourteenth hospital day the patient used a 25 per cent solution of lithium chloride as seasoning on his food, ingesting a total of 17 Gm. of the salt in thirteen days. On the fourth hospital day 30 pounds (13.6 Kg.) of ascitic fluid was removed by abdominal paracentesis. While receiving lithium he complained of moderate generalized weakness and fatigue. However, during this period fluid was draining copiously from his paracentesis wound with resulting loss of sleep.

During this first period of lithium chloride administration about 37 per cent of the lithium ingested over the thirteen day period was recovered in the urine. The amount of lithium chloride excreted in the urine per 24 hour period varied from 0.25 to 1.26 Gm. Two days after lithium was started there was an insufficient concentration of it in the plasma and ascitic fluid to be detected by the flame photometer. During this period there were no significant changes in the plasma levels of chloride, sodium or potassium. The plasma carbon dioxide-combining power fell from 54 to 36 volumes per cent.

On the forty-third hospital day he was started on a diet containing approximately 2 Gm. of sodium chloride. From the fifty-fifth to the seventieth hospital day he received lithium chloride, 1 Gm. in a glass of water three times daily after meals. He ingested a total of 43 Gm. in sixteen days. During this time he complained of moderate weakness and fatigability. He was drowsy and slept during most of the day. These symptoms gradually disappeared after lithium was discontinued.

During this second period on lithium abdominal paracentesis was repeated. Only 350 cc. of fluid was obtained, but it continued to drain from the wound and he lost 43 pounds (19.5 Kg.) in the next four days. There was no change in his symptoms during this time. During this period of study 46 per cent of the lithium ingested over the sixteen days was recovered in the urine, including measurable amounts excreted for seven days after lithium intake was stopped. Traces could still be detected in the urine eleven days after administration was discontinued. The highest concentration detected both in plasma and ascitic fluid was 2.2 milliequivalents per liter, eight days after lithium was started. On the fifth day after stopping the drug by mouth there was 1.0 milliequivalent per liter in the plasma. There was no appreciable change in blood or plasma specific gravity, hematocrit, blood urea nitrogen, carbon dioxide-combining power, or plasma levels of sodium, potassium and chloride during this period.

CASE 3.—This patient, I. B., was a 60 year old white man who entered the hospital because of an acute, posterior myocardial infarction. His recovery from the infarct was uneventful and he was discharged on the seventy-fourth hospital day. He was treated with bed rest and a regular ward diet.

Lithium chloride was given to him from the twenty-eighth to the thirty-fourth hospital day in order to study its concentration in the plasma, its urinary excretion and any toxic symptoms. The dosage given was 1 Gm. in water two or three times daily after meals, to a total of 16 Gm. in seven days.

After receiving the lithium chloride for two days, he complained of dryness of the mouth and drowsiness. This latter increased in severity until the drug was discontinued. On the fifth day he complained of nausea, fatigue, marked weakness of the hands and blurring of vision. On the sixth day there was a coarse tremor of his hands which increased with movement. The drug was discontinued the next morning. The blurring of vision and tremor had disappeared by the second day. About five days later all symptoms coincident with administration of the drug had disappeared.

While he was receiving lithium there was a diminution of daily urine volume, probably due to the decrease in fluid and food intake resulting from the anorexia and nausea. Lithium was still being excreted in the urine five days after its administration had been discontinued. Of the 16 Gm. of lithium chloride ingested during seven days, 92 per cent had been excreted in the urine during the twelve day period. The highest plasma lithium level observed was 3.3 milliequivalents per liter on the fifth and last day of its use. Two days later the level was 2.3 milliequivalents per liter.

During the time he was receiving lithium there was no significant change in the plasma specific gravity, blood urea nitrogen, plasma chlorides or plasma carbon dioxide-combining power. The blood specific gravity increased from 1.0615 to 1.065, and the hematocrit reading from 49 to 53.5, probably because of decreased fluid intake.

CASE 4.—The following is a case report of a patient who was treated outside the hospital by several different physicians. His private physician has given us permission to report the following data.

A 60 year old white man with arteriosclerotic and hypertensive cardiovascular disease who had been in severe chronic heart failure for two years used 50 Gm. of lithium chloride on his food over a hundred and fourteen day period. He was managed in his home with digitalis, frequent injections of mercurial diuretics and restricted sodium chloride intake. About two weeks after beginning the use of lithium chloride he began to notice lethargy and irregular tremors of his hands, worsened by movement. Four weeks later tremors involved all extremities, speech was slurred, and tapping the face to elicit a Chvostek sign caused contraction of all the muscles of that side of the face and neck. Weakness was so severe that the patient was bed ridden. Serum electrolyte studies revealed a sodium level of 119.5 milliequivalents per liter; chloride, carbon dioxide-combining power, calcium and potassium levels were normal. Because of the low serum sodium his sodium chloride intake was increased. Within two weeks the serum sodium had risen to 133 milliequivalents per liter, with slight improvement of the tremor but no change in the weakness. During the next six weeks he was seen in consultation by numerous competent physicians and various medications were given: calcium gluconate and hypertonic glucose intravenously, numerous vitamin preparations, triple potassium salts, diphenhydramine hydrochloride, belladonna alkaloids, alcohol and barbiturates—all to no avail. Finally, lithium chloride was discontinued. For three days the tremor became worse. Thereafter, the weakness and lethargy rapidly disappeared. At the end of ten days there was only a faint trace of tremor when performing skilled acts.

SURVEY OF THE LITERATURE

In the middle of the last century lithium was popular as a treatment for gout until it was shown to be of little value.[1] It is rapidly absorbed after oral or parenteral administration and is widely distributed in body tissues.[2] Good[1] found higher concentrations of it in muscle than in liver. Others found that it appeared in the cerebrospinal fluid only after three days.[3] Excretion is principally in the urine, but small amounts are found in the feces and saliva.[4]

A number of toxic effects have been ascribed to lithium,[5] involving the central nervous system, the gastrointestinal tract and the heart. Kolipinski[6] has recorded 2 cases of toxicity in human beings after the ingestion of lithia tablets (he fails to give the dose). He described general prostration, muscular weakness of a degree to impair locomotion and a constant fine tremor of the hands. Both patients recovered three to five days after stopping the drug. Cleaveland[7] recorded his own experiences after taking 8 Gm. in 2 Gm. doses over twenty-eight hours. Three to four hours after the first dose he noted slight fulness of his head and dizziness. Shortly following the third dose his vision became so blurred he was able to read only the largest headlines of a newspaper. Dizziness and tinnitus were marked. He experienced great general weakness and severe tremor. Vertigo was present. The following morning the weakness and tremor were so intense that he began to stagger and was forced to retire to his bed. The eye and ear symptoms persisted for about one and one-half days, and the weakness and tremor for five days after the last dose. Several months later he repeated this experiment using smaller doses and experienced similar but less marked symptoms.

TABLE 2.—*Summary of Toxic Symptoms and Lithium Plasma Levels and Excretion in 4 Cases*

Case	Patient	Highest Plasma Concentration, MEq./L.	Amount Ingested: Total Gm.	Amount Ingested: Days	Amount Ingested: Average Daily, Gm.	Amount Excreted in Urine: Gm.	Amount Excreted in Urine: Percentage	Symptoms of Toxicity
1	C. D.	4.8	13	3	4.3	5.2	40	Drowsiness, weakness, tremor, anorexia, nausea, neuromuscular irritability
2	A. C. (1st)	...	17	13	1.3	6.3	37	Slight weakness and drowsiness
	A. C. (2d)	2.2	43	16	2.7	19.8	46	Moderate weakness and drowsiness
3	I. B.	3.3	16	7	2.3	14.7	92	Weakness, tremor, drowsiness, anorexia, nausea, blurring of vision
4	......	...	53	114	0.5	....	..	Drowsiness, weakness, tremor, neuromuscular irritability

Other investigators have noted the central nervous system manifestations of lithium toxicity. Cushny[4c] spoke of a "depressant action on the motor nerves." Wood,[5f] discussing Binet's work with mammals, mentioned feebleness, convulsions, paralysis of the peripheral nerves and affection of the muscles evidenced by peculiar fibrillary contractions, followed by death. He stated in his book,[5e] "In 20 grain doses I have seen it produce severe general prostration, amounting almost to general paralysis, in a feeble adult female, but have given it very largely to other patients without inducing any constitutional symptoms."

Lithium has been shown to cause gastrointestinal symptoms—nausea, vomiting and diarrhea—in cats. Although older textbooks stress these as prominent symptoms in human toxicity,[8] neither Menzani[9] nor Cleaveland[7] noted any such effects after taking the drugs themselves.

Frequent statements can be found in the older literature that lithium salts depress the heart's action, cause a fall in blood pressure, weaken contraction and cause arrest in diastole,[10] but experimental work on this phase of lithium metabolism is both scanty and inconclusive.

The well known effects of lithium on the embryologic development of lower animals were discussed by Needham.[11] MacLeod[12] has demonstrated that low concentrations of lithium produce a decided reduction of the glycolytic activity and motility of human spermatozoa suspended in Ringer's solution. He suggested the possibility that interference with glucose metabolism in the muscles may be the mechanism by which lithium produces muscular weakness.

COMMENT

Our main purpose in presenting these cases is to bring attention to the possibility of severe toxic effects which may be caused by the ingestion of lithium chloride.

The dosage used, the plasma levels, the amount excreted, and the toxic symptoms are summarized in table 2. In each of the five periods of study in 4 patients symptoms of toxicity were observed. All patients complained of weakness and drowsiness. Although patient 2 and patient 3 received approximately the same daily dose the symptoms were far more severe in patient 3. The plasma concentration of lithium was higher in the latter patient. It is possible that these findings may be partially explained by the trapping of lithum in the large volume of extracellular fluid (ascites and edema) present in patient 2. Patient 1 took the largest average daily dose, had the highest plasma concentration and manifested the most severe symptoms.

In the patients presented the only gastrointestinal symptoms were nausea and anorexia in patients 3 and 1. In patient 3 the nausea immediately followed ingestion and may have been due to local irritation. Patient 1 ingested far more than patients ordinarily use to season their food. We have not observed definite evidence of effect on the heart. The principal symptoms observed seem to indicate an effect on the nervous system, muscles or both. We have found lithium present in significant concentration in the cerebrospinal fluid, and Good has demonstrated its presence in large amounts in muscle. Further work seems necessary to determine the mechanism by which lithium produces these effects. The meager data presented in tables 1 and 2 do not justify any extensive conclusions. However, we feel that these data are perhaps suggestive that lithium is more slowly excreted in patients who have impaired renal function due to cardiac failure or cirrhosis with ascites, as in cases 1, 2 and 4. Patient 3, who had no evidence of disordered renal function, excreted a much higher percentage than the others. It should be pointed

out that in none of these patients was the urine followed long enough to determine the total amount of lithium eventually excreted. More investigation will be required to determine the rates of absorption and excretion, and the correlation between plasma levels and toxic manifestations.

We have seen a number of patients who have used small amounts of lithium chloride as a salt substitute without harmful effects. However, our experience with case 1 well emphasizes the danger that patients on a low sodium diet may use dangerously large amounts of lithium to satisfy their craving for salt. This case also illustrates the difficulty of counteracting the toxic manifestations in an already severely ill patient. It must be admitted that we do not know how to hasten excretion of lithium from the body or to counteract its toxic effects.

Case 1 illustrates the picture of acute toxicity. Case 4 shows how insidiously the symptoms of chronic toxicity may develop in a patient taking small doses over a long period of time.

SUMMARY AND CONCLUSIONS

Four cases are presented in which lithium chloride caused toxic symptoms — drowsiness, weakness and generalized tremors. The death is reported of a patient in a precarious state of cardiac compensation who showed severe toxic effects following the ingestion of excessively large amounts of lithium chloride with his diet.

Review of the literature reveals that very little work has been done on the pharmacology of lithium in recent years, and its effects on the various metabolic processes are poorly understood.

Caution should be used in prescribing lithium, especially for those patients on a low sodium diet who might use it in excessive quantity. Patients using lithium should be carefully watched for the development of both acute and chronic toxic manifestations.

EDITORIAL NOTE

Lithium is one of the chemical elements belonging to the group called the alkali metals of which sodium and potassium are best known. It was first discovered in 1817. Lithium is the lightest and most reactive metal known and has physical and chemical properties which are similar to sodium and potassium, but the lithium atom differs from the atoms of other alkali metals in weight and size. The name is derived from the Greek word for stone, and lithium was so called because it was considered never to be present in plant and animal matter. However, it does occur in both in minute amounts.

The salt, lithium chloride, has a molecular weight somewhat lower than that of sodium chloride, and it occurs as white, deliquescent crystals. Any toxic effect from lithium preparations is probably not due to the salt as such but to the lithium ion itself.

Lithium can be identified in body tissues and fluids. Lithium compounds show a characteristic crimson-colored flame, and lithium chloride is readily separated from similar alkali chlorides by differential solubilities in higher alcohols. This allows the separated lithium chloride to be analyzed by standard procedures.

Lithium chloride is commonly present in carbonated beverages and in mineral waters in a highly diluted solution. It has also been used in pyrotechnics, as a dehumidifying agent for refrigerant systems, and for soldering aluminum.

The preparation westsal® is a solution of which the composition was found by the American Medical Association Chemical Laboratory to be approximately:

Lithium chloride	25.0 per cent
Citric acid	0.2 per cent
Potassium iodide	0.01 per cent

RHEUMATOID SPONDYLITIS

Its Early Diagnostic Features and Management

RICHARD Z. QUERY, Jr., M.D.
Charlotte, N. C.

Rheumatoid arthritis of the spine is a commonly encountered cause of backache, especially that occurring among male patients of the second and third decades of life. The disease is characterized by periods of active symptoms which alternate with periods of partial or complete freedom from discomfort. After a variable number of years (average fifteen to twenty-five) the process becomes permanently inactive. The end result of the disorder is the production of the so-called "poker spine."

In the evolution of the current concept of rheumatoid arthritis of the spine many synonyms are still in use. The varied terminology serves to confuse one not thoroughly familiar with the fact that involvement of the sacroiliac joints and lumbosacral, dorsal and cervical levels of the spine represents the usual progression of one and the same disease—rheumatoid spondylitis. Synonyms frequently encountered in the literature are Marie-Strümpell's disease, spondylitis ossificans ligamentosa of Knaggs, von Bechterew's syndrome, ankylosing spondylitis, adolescent or juvenile spondylitis, spondylitis ankylopitica and spondylarthritis. The designation for this disease which is recommended by the American Rheumatism Association is "rheumatoid spondylitis."

INCIDENCE

Sex.—Existing reports stress the disparity in incidence of rheumatoid spondylitis in the two sexes.[1] Herrick and Tyson recognized 10 cases (8 male and 2 female patients) during a period of five years. An incidence of 0.2 per cent of all new patients. Hare reported 21 cases (19 male and 2 female patients) among 1,179 cases of arthritis during a two year period at the Lahey Clinic. Polley and Slocumb reported 1,035 cases (931 male and 104 female patients) from 1935 to 1943, inclusive, at the Mayo Clinic.

Fletcher[2] reported a higher incidence in female patients than most observers. He studied 68 patients, 32 of which were female.

I have recognized the disease in 32 patients, an incidence of 4.9 per cent of all new patients during a two year period in private practice, 12 of whom were female. The sex incidence of total new patients seen was approximately the same. Obviously, this series of patients is too small for the data presented to be of statistical significance and is contrary to that of most observers. However, I do not feel that I have been too ambitious in making the diagnosis in women; the criteria for diagnosis have been strictly observed.

Military.—Rheumatoid spondylitis was found to be a fairly common cause of backache among young adult

soldiers in both World War I[3] and World War II.[4] In one Army General Hospital in World War II, 7.5 per cent of all patients admitted to the medical service with complaints referable to the musculoskeletal system and 18 per cent of those admitted with chronic back complaint proved to have rheumatoid spondylitis.[4a]

There were 1,084 cases of rheumatoid spondylitis in 6,000 consecutive admissions to the Army Rheumatism Center, Army and Navy General Hospital, during a period of two years.[5] These comprised 18.1 per cent of patients with all types of rheumatic diseases. There were 779 with spondylitis alone and 305 with spondylitis plus peripheral joint involvement. There were 1,127 patients with peripheral rheumatoid arthritis alone. These data reveal that approximately 1 out of every 5 patients admitted to this institution had rheumatoid spondylitis and approximately one half of all patients with rheumatoid arthritis (2,211) had spondylitis (1,084), with and without peripheral joint involvement. Moreover, nearly as many soldiers were admitted with spondylitis as were admitted with peripheral rheumatoid arthritis alone. These figures differ greatly from those in reports based on civilian practice.

The relatively high incidence of the disease in soldiers has been explained by (1) the preponderance of males at an age group for which the disease has a predilection and (2) the influence of strenuous activity and adverse living conditions in bringing to light cases of mild and early disease, including previously present but undiagnosed conditions in many.[4a]

Civilian.—In contrast to the incidence of this disease reported among soldiers, the ratio of peripheral rheumatoid arthritis to rheumatoid spondylitis among members of the civilian population has been variously reported as 11 to 1, 13 to 1 and 19 to 1.[6] The reason for this disparity has not been clearly shown. It may be that a consideration of members of the civilian population engaged in pursuits similar to that of military personnel would result in a ratio more comparable to that encountered among soldiers.

PATHOLOGIC ASPECTS

Rheumatoid spondylitis is a chronic, usually progressive, inflammatory disease of unknown origin of the synovial joints of the spine and adjacent soft tissues. The process almost always begins in the sacroiliac joints and usually progresses to involve the synovial (facet or apophyseal) joints of the lumbar, thoracic and cervical regions and the costovertebral articulations. The pathologic changes in the joints consist of synovitis, chondritis, juxta-articular osteitis and ankylosis. There occur painful spasms and contractures in the paravertebral muscles. As the disease progresses, calcific and later osseous changes develop in the paraspinal ligaments. The vertebral bodies frequently show secondary demineralization. The intervertebral disks are not affected.

Space will not permit a discussion of the relationship between peripheral rheumatoid arthritis and rheumatoid spondylitis. Suffice it to say that most American investigators favor the concept that rheumatoid spondylitis is not a separate pathologic entity, but is simply an expression of rheumatoid arthritis as it involves the spine.[7]

DIAGNOSIS

Rheumatoid spondylitis is one of the most prevalent and most crippling of the chronic diseases affecting the spine. Unfortunately, it has evoked little interest other than among physicians particularly interested in diseases of the musculoskeletal system. The diagnosis is often mislabeled and postponed for several years after onset, when it may be too late to expect good therapeutic results. Early diagnosis should not be difficult, however, if physicians are familiar with the characteristic clinical and roentgenographic features of the disease.

Symptoms.—The usual initial complaint of the patient is that of aching, soreness and stiffness of the lower part of the back. Early in the course of the disease the symptoms are mild and of only a few days' duration. However, symptoms recur at varying intervals. The subjective manifestations are usually worse in the mornings on the patient's arising and after periods of rest during the day and tend to improve with activity. The symptoms are generally aggravated by inclement weather and are frequently worse preceding weather changes. Periods of remission often occur spontaneously in the hot dry months of the year. Temporary relief from discomfort is obtained by the local application of heat and the use of salicylates. The discomfort is often pronounced at night, frequently waking the patient. As the disease progresses, the aching and stiffness tend to become persistent and remissions are less common until the process is "burned out."

Less frequently the onset is acute and is characterized by sudden disabling low back pain, often described as "lumbago." The condition in approximately 10 per cent of the cases is initiated by sciatica.[4a] Occasionally the initial symptoms are thoracic girdle pains or inguinal and thigh pains of either a sharp stabbing or dull aching character. Close questioning will usually reveal previous low back symptoms, however, probably mild in character.

As the disease progresses to involve the synovial membranes of the lumbar apophyseal joints, pain, soreness and stiffness of the type described increase. Acute "catches" or attacks of "lumbago," precipitated by motion and trauma, are not uncommon. The lower part of the back becomes less mobile, and the patient notices that he cannot bend forward as readily or completely as formerly.

When the dorsal segment is affected, thoracic girdle pain and chest pain on forced inspiration, coughing or sneezing are often present.

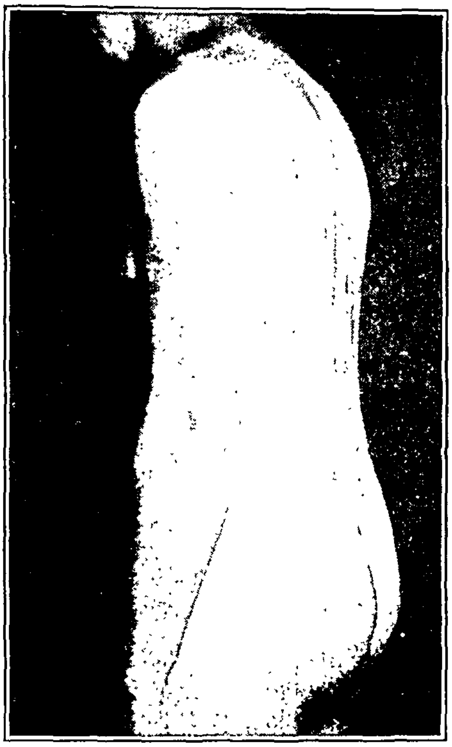

Fig. 1.—Rheumatoid spondylitis, moderately advanced, with straightening of lumbar part of the spine. The muscle atrophy in the lumbar region ("ironed out" appearance) may be noted.

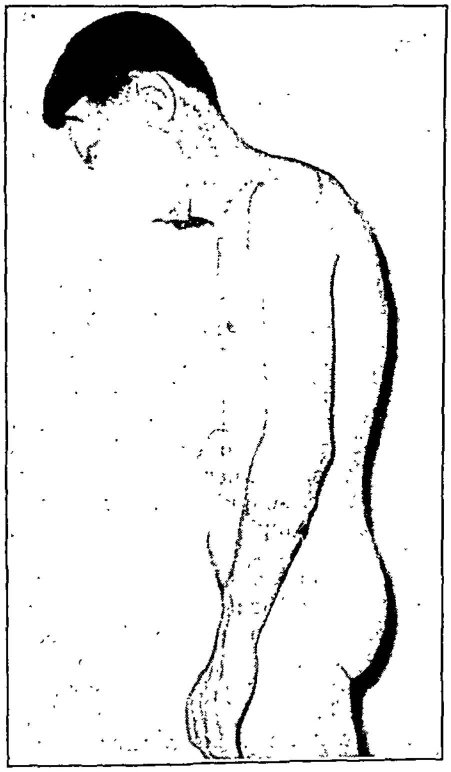

Fig. 2.—Rheumatoid spondylitis involving the entire spine. The flattened anterior part of the chest and thoracic kyphosis may be noted. The neck is protruded forward, and lumbodorsal stoop is apparent.

With involvement of the cervical spine the neck becomes stiff, motion is limited in all directions and the head is often protruded forward. The patient may have to pivot his entire body in order to look in a lateral direction.

Clinical Signs.—When the disease is localized to the sacroiliac joints, the most frequent positive physical observations are: 1. Tenderness and pain over these joints on palpation and first percussion and precipitation of pain on motion or stretching of the sacroiliac joints. 2. Lumbar muscle spasm may be present. 3. Motion of the spine may not be discernibly affected. Positive physical observations may be absent if the disease is mild or if the sacroiliac joints are ankylosed.

With extension of the process to the joints of the lumbar portion of the spine there is a decrease in the normal lumbar lordosis, paravertebral lumbar muscle rigidity, limitation of lumbar motion and atrophy of the lumbar muscles which ultimately result in a flattened or "ironed out" appearance (fig. 1).

When the dorsal region is involved, the patient may exhibit pronounced postural deformity unless preventive or corrective measures have been previously instituted. Chest expansion is diminished. The anterior chest wall is flattened and associated with thoracic kyphosis (thoracolumbar stoop). Tenderness is elicited by percussion over or just lateral to the dorsal spinous processes. Motion of the thoracic part of the spine is limited. Spasm and/or atrophy of the muscles of the dorsal level is present (fig. 2).

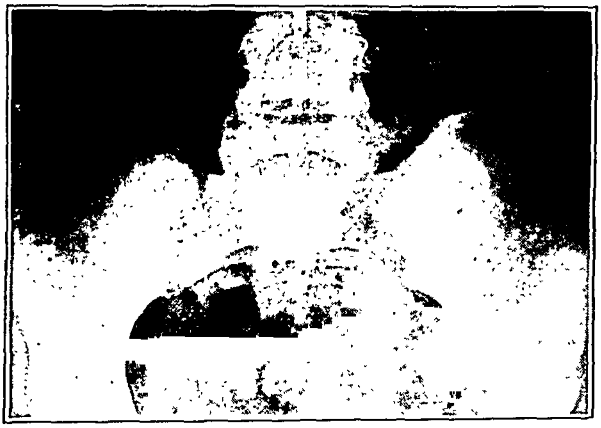

Fig. 3.—Mild rheumatoid spondylitis in a woman aged 48, with symptoms of three years' duration. The sacroiliac joint margins are blurred and indistinct. Juxta-articular increase in bone density in the ilium and sacrum may be noted.

When the neck becomes affected there is pain on forced motion and tenderness on palpation and percussion over the posterior aspect of the neck.

Roentgenographic Features.—The roentgenographic features of rheumatoid spondylitis are characteristic. However, as in peripheral rheumatoid arthritis, definite symptoms and positive physical observations may be present for many months before structural changes are roentgenographically demonstrable. The earliest roentgen changes in rheumatoid spondylitis are seen when the disease has progressed sufficiently to produce alterations in the cartilage and juxta-articular bone of the sacroiliac joints. The changes are usually bilateral, but may be more pronounced on one side than the other. Definite changes may be apparent in one side for many months before they can be demonstrated in the other. The earliest changes are characterized by blurring or haziness of the joint margins. Later the margins appear irregularly mottled and serrated, and the juxta-articular portions of the sacrum and ilium may show increased density, spotty osteoporosis or both (figs. 3 and 4). These changes are particularly pronounced in the caudal third of the joint. With continual progression complete ankylosis results (fig. 5).[8]

The roentgen changes in the apophyseal joints are not as definite or as constant as those in the sacroiliac articulations. The results are often disappointing, even with special technics. The alterations, when present, are usually limited to one or a few scattered joints and qualitatively the changes are similar to those described in the sacroiliac joints. Rarely are apophyseal changes seen without accompanying evidence of sacroileitis.

The roentgenographic changes in the thoracic region may consist of scattered apophyseal involvement, which is technically even more difficult to demonstrate than changes in the lumbar segment. With progression of the disease to involve the dorsal portion of the spine, however, there may be calcific deposits in the paraspinal ligaments. Calcification most often begins in the lower thoracic and upper lumbar levels of the spine. It may vary from a fine penciling of calcium in the anterior spinal ligament to extensive calcification and ossification, producing the well known roentgenographic picture of a "bamboo spine" (figs. 5 and 6).

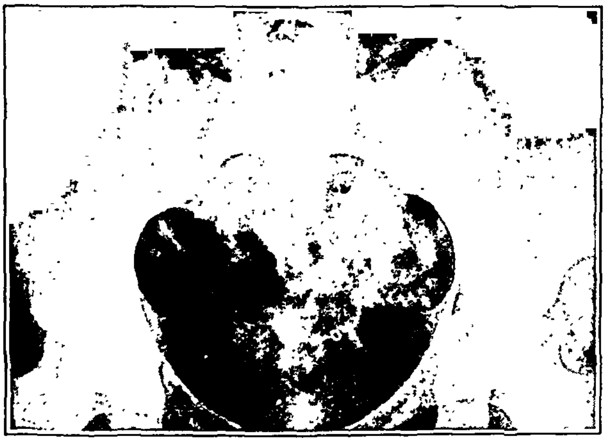

Fig. 4.—Moderate rheumatoid spondylitis in a woman age 20 with symptoms of six months' duration. The sacroiliac joints are irregularly mottled. Juxta-articular sclerosis is pronounced. Narrowing of the left hip joint may be noted.

The roentgen observations in the cervical region are similar to those described in the thoracic region.

Laboratory Observations.—The erythrocyte sedimentation rate is elevated in approximately 80 per cent of the cases of active rheumatoid spondylitis.[4a] It is the most helpful and consistent laboratory aid to diagnosis with the exception of roentgenographic changes in the sacroiliac joints. Patients with mild slowly progressive conditions may have repeatedly normal sedimentation rates, while in severe conditions it is almost invariably elevated. Mild hypochronic anemia is present in about 30 per cent of cases and usually runs parallel with the degree of severity of the disease.[4a]

The cerebrospinal fluid has been studied in patients with rheumatoid spondylitis, and the initial manometric pressure, cell counts, concentrations of sugar and colloidal gold reactions are generally normal.[9] In approxi-

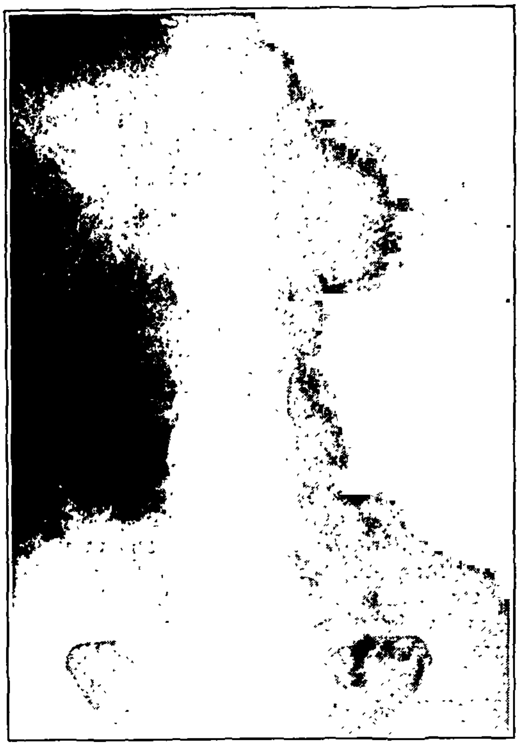

Fig. 5.—Severe rheumatoid spondylitis in a woman aged 48, with symptoms of thirty years' duration. The sacroiliac joints are ankylosed. Extensive ligamentous calcification is present, producing the terminal picture of a "bamboo spine." Secondary demineralization of vertebral bodies, of the sacrum and the ilium, may be noted.

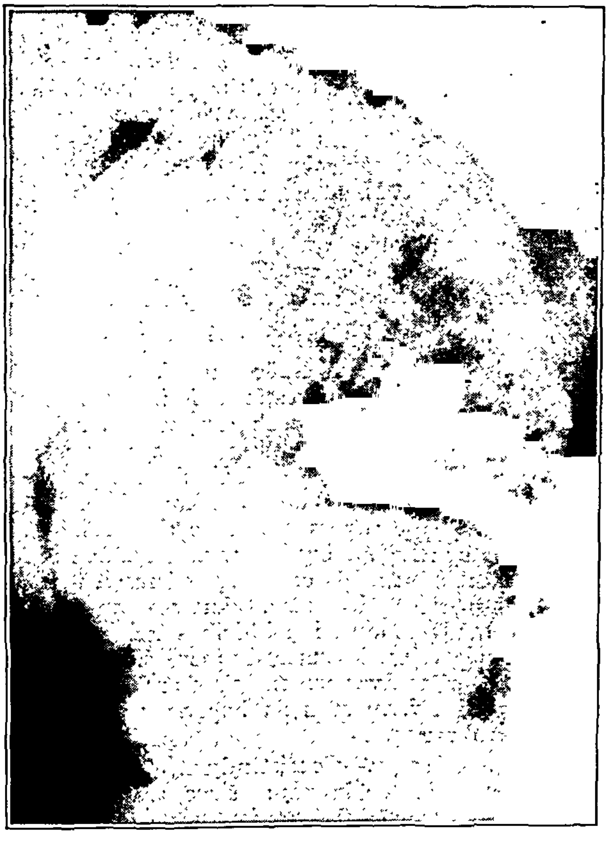

Fig. 6.—Roentgenogram of the same patient as that of figure 5. Severe dorsal kyphosis and calcification of anterior spinal ligaments in the lower thoracic region may be noted.

mately 40 per cent of cases of this disease the total protein content of lumbar spinal fluid has been found to be increased from 45 to 105 mg. per hundred cubic centimeters. The protein content bore no consistent relationship to the duration of the disease or to the extent of cephalad progression but was apparently related to the severity of the spondylitis.[10]

CLINICAL COURSE OF RHEUMATOID SPONDYLITIS

Rheumatoid spondylitis usually follows a fairly characteristic clinical pattern. The initial sacroiliac involvement is usually followed by upward progression, which may finally involve the entire spine. One area of the spine may be active and symptomatic, while another is quiescent and asymptomatic. The active process may subside either temporarily or permanently at any level of the spine.

When the patient is first seen, the symptoms and observations are variable and depend on the duration, severity and areas of the spine actively or inactively involved at the time. Mild conditions may continue for many years, producing little or no back disability or general constitutional symptoms, such as fever, malaise, fatigue and weight loss. Patients in whom the process is severe and rapidly progressive may become disabled within a few months; in such cases constitutional symptoms are usually a prominent feature, particularly if peripheral joints are concomitantly involved.

I have been impressed by the relatively milder character of the disease in women as compared to the disease in men. The roentgen changes in the sacroiliac joints are usually less pronounced, and rarely have I found the disease advanced enough to demonstrate calcific and osseous changes in the paravertebral ligaments. Ligamentous calcification was seen in only 1 of the aforementioned 12 cases. Low back complaints in women seem to be expected and taken for granted. The condition in 3 of the patients was diagnosed as "idiopathic" low backache without roentgen examination. In 2 cases low back complaints were ignored because of predominating symptoms in peripheral joints; yet the diagnosis of rheumatoid spondylitis could be made in all of them by physical and roentgen observations. I wonder whether physicians are not overlooking cases of rheumatoid spondylitis in women by not examining them more carefully and completely.

TREATMENT

There is no known specific cure for rheumatoid spondylitis. However, if treatment is instituted early and continued faithfully, much can be accomplished toward relieving or ameliorating the symptoms and preventing and correcting spinal deformity. The patient's confidence and cooperation must be obtained if good therapeutic results are to be expected. This is best done by familiarizing him with the nature of his disease and its potentially crippling end result if treatment is neglected. He should know what may be expected from treatment if faithfully executed. With this knowledge, he will usually be more diligent in the performance of the various exercises and other home measures which form such an important part of the therapeutic regimen.

Roentgen Therapy.—Consistently favorable reports have appeared in the literature since 1930 regarding the results of roentgen therapy for rheumatoid spondylitis.[11] In a series of 52 patients with rheumatoid spondylitis treated with roentgen rays, 72 per cent were reported to have obtained notable subjective improvement and 50 per cent experienced definite objective improvement.[7c] In some instances, all clinical evidences of the disease disappeared, suggesting that at times the disease may possibly become arrested as a result of roentgen therapy. In this study possible psychic effect was ruled out by having a control group of patients go through the same routine as those in the roentgen therapy group; however, the former received no actual irradiation (the rays were blocked by lead screens without the patient's knowledge). No significant beneficial results were obtained in the control group.

This work was recently confirmed and extended.[12] This report is concerned with the treatment of 75 soldiers with rheumatoid spondylitis at an army rheumatism center. The results indicated that roentgen therapy applied to the involved regions of the spine was of definite value in rheumatoid spondylitis: Ninety-two per cent of the patients so treated were improved symptomatically, and 68 per cent were improved objectively. Of those receiving "psychic roentgen therapy," objective improvement occurred in 8 per cent and subjective improvement in 28 per cent. Best results were obtained when roentgen therapy was combined with deep breathing and postural exercises.

The technic of therapy used in both of the aforementioned groups was essentially the same and is now the one most commonly used in this country: 200 kilovolts with 0.5 mm. of copper and 1 mm. of aluminum filtration. The usual field was 10 by 15 cm. for the lumbosacral region and 8 by 20 cm. above the lumbosacral region. The dosage consisted of 200 r (measured in air) per portal every two days for three doses. Three doses per portal (a total of 600 r) constituted a series. Each patient received three series at thirty to forty-five day intervals.

Roentgen therapy should be directed to the areas of the spine symptomatically and clinically involved and not just confined to the areas roentgenographically involved.[12] It has been advocated that additional roentgen rays be given to symptomatic regions if recrudescences occur.[13]

It cannot yet be determined whether roentgen therapy actually alters the course or activity of the disease process or whether it simply produces an analgesic effect. Controlled studies over a period of years will determine this.

Prevention and Correction of Postural Deformities.—Much can be accomplished with relatively simple exercises in preventing postural deformities if these are carried out regularly and diligently for a period of years. It should be stressed that the exercises given by the physical therapist in the hospital or in the physician's office must be carried out at least twice daily at home. These should include trunk stretching, hamstring and calf stretching, deep breathing and exericses for the correction of special postural defects. The exercises often may be carried out more readily and less painfully if acetylsalicylic acid and heat (hot tub baths) are given thirty minutes beforehand. The patient must be taught to become "posture conscious" and assume a proper stance at all times. The spondylitic patient should use a firm bed (boards under a felt or latex mattress) and no pillow. A soft pillow under the lumbar region will help to maintain the normal lumbar curve and a firm blanket roll under the neck will increase spinal hyperextension. These measures will help prevent postural deviations and may even correct minor and early deformities.

Spinal braces should be reserved for patients with deformities that are more advanced and whose postures cannot be adequately corrected or maintained by exercises alone. The same is true for hyperextension frames and beds and plaster half-shells. In some cases of severe deformities plaster half-shells and braces may aid in controlling muscle spasm and pain.

General Measures.—Measures to maintain and improve the general health and strength are just as important in the treatment of spondylitis as in peripheral rheumatoid arthritis. Complete bed rest is rarely advisable except for patients with severe rapidly progressive disease. The usual patient with mild or moderately severe disease should get eight to ten hours of bed rest at night and an additional one or two hours in bed at noon. The back should be protected from undue physical activity at all times. Weight should be regulated by administration of a high caloric diet to the malnourished and a low caloric diet to the obese patient. Ample vitamin supplements should be given and iron salts if hypochromic anemia is present. Acetylsalicylic acid (40 to 60 grains [2.6 to 3.9 Gm.] per day) should be given as often and in the amount necessary to control pain. Home physical therapy in the form of baking, infra-red heat, massage and thermal baths is often of help in giving symptomatic relief.

Other Measures.—Foreign protein reactions by the intravenous injection of typhoid vaccine may possibly be of value in altering the course of the disease. Whether actual remissions may be produced or not is questionable. Gold salts have been used in a small number of reported cases and are said to be of no value.[14]

COMMENT

The diagnosis of rheumatoid spondylitis is not difficult when the disease is advanced. Cases of severe disease with "poker back" deformity are generally readily recognized. The diagnosis of early disease is frequently difficult, however, and may be missed, unless the disease is considered in every patient, especially young men with chronic back complaints.

Chronic recurrent or persistent low back aching and stiffness, with or without catching pains, in young adults is strongly suggestive of this disease. Radicular pains, particularly sciatic and thoracic, are common symptoms and may overshadow previous or present mild low back discomfort. Sciatic pain may alternate from side to side and is usually not severe. These symptoms when accompanied with muscle spasm, flattening of the normal lumbar lordosis, limitation of lumbar motion, sacroiliac and lumbar tenderness to percussion and palpation, an elevated sedimentation rate, perhaps mild constitutional symptoms and roentgenographic alterations in the sacroiliac joints definitely establish the diagnosis. It is important to remember, however, that one or more of the aforementioned symptoms and observations may be absent, particularly in cases of mild disease.

Sacroiliac joint alteration demonstrated by roentgen examination is the most useful and reliable laboratory aid in the diagnosis of rheumatoid spondylitis; however, there may be an interval of several months to two or three years after the onset of symptoms before definite roentgenographic changes can be demonstrated.[15] This interval is usually more than compensated for by the patient's tardiness in consulting a physician; usually when the patient is first seen, roentgen changes will be present.[1d] The opinion has been expressed that, although the disease may be suspected clinically, an unequivocal diagnosis should not be made when there are no demonstrable roentgen changes.[4a]

The sedimentation rate is elevated in approximately 80 per cent of the cases of active rheumatoid spondylitis. An elevated sedimentation rate is of particular significance when the symptoms and observations are suggestive but the roentgenograms are still normal. There is no elevation of the sedimentation rate in the disorders from which rheumatoid spondylitis must be differentiated: osteoarthritis, muscular rheumatism of the back and ruptured intervertebral disk.

Persistent symptoms referable to the back occurring in a person with peripheral rheumatoid arthritis usually indicate the association of rheumatoid arthritis of the spine.

SUMMARY

The criteria for the diagnosis of rheumatoid spondylitis are presented. An observation relative to the difference in sex incidence among a small group of private patients with this disease is reported. This observation is at variance with that generally reported. There is no known specific cure for rheumatoid spondylitis. However, if treatment is started early in the course of the disease and continued faithfully, much can be done toward preventing and even correcting spinal deformity. The therapeutic regimen should be well rounded and should include: maintenance of a good general state of health, regulation of rest, diligent execution of deep breathing and postural exercises, appropriate physical therapeutic procedures and roentgen therapy to the segments of the spine that are actively involved clinically.

ABSTRACT OF DISCUSSION

Dr. Edward F. Rosenberg, Chicago: Dr. Query's report of 32 cases encountered within a relatively short time, in his own practice, is indicative of the numerical significance of this disease in every American community. The incidence increases regularly wherever interest in rheumatoid spondylitis appears. It is prevalent, but often goes unrecognized. The disease is often undiagnosed for years after symptoms appear. The patients frequently receive a diagnosis of lumbago, fibrositis, muscular rheumatism, chronic low back strain, renal disease or sciatica. Meanwhile, time is lost, and in some instances irreparable deformities are allowed to appear. I regret that in many instances spondylitis goes unrecognized until the spine assumes the bamboo appearance associated with most advanced and extensive stages. Dr. Query's observation of 12 female patients among 32 patients with rheumatoid spondylitis is remarkable. The literature reflects wide variations in sex incidence in different series. All agree that rheumatoid spondylitis is more common among men; in fact, some doubt whether rheumatoid spondylitis ever occurs in female subjects. On the other hand, the incidence in female patients was 47 per cent in one series. It is not possible to explain such wide variations. Perhaps criteria for diagnosis are too loose in some series and the incidence in female patients consequently higher than is proper. In others criteria are, doubtless, too rigid. The disease certainly occurs in female patients and runs a course in them similar to that in male patients. The incidence of female patients in my material is 10 per cent. Abnormal elevations of protein in the spinal fluid have been observed in nearly 40 per cent of the cases in which this phenomenon has been studied—an important point to remember. The early symptoms of rheumatoid spondylitis in some cases consist of recurring episodes of sciatica, like those in patients with protruded disks. High levels of cerebrospinal fluid protein cannot therefore be used to prove the diagnosis of protruded disk. That diagnosis must be made on more secure grounds. The wide popularity of roentgen therapy for spondylitis may be misleading. One gathers the impression from some writers that this is the only measure of therapy needed. Dr. Query rightfully stresses that this is not the case. Roentgen therapy may produce some analgesia and even some objective improvement, but the main problem of the patient's care remains. He is still suffering from rheumatoid spondylitis. His disease will probably progress and will require every aid—hygienic measures, orthopedic care, physical therapy and other common sense measures at one's command. Doctors have a grave responsibility to learn to recognize this condition earlier and to see that the patients are given the benefit of intensive and early treatment.

[15] Boland and Present.[4a] Boland and Shebesta.[8]

Dr. Richard T. Smith, Philadelphia: Rheumatoid spondylitis is probably misdiagnosed in 100 per cent of cases in which the disease has persisted from months to years. Any patient with recurrent low back pain deserves a careful study for the possibility of spondylitis. The majority of cases do occur between the ages that were pointed out, but rheumatoid spondylitis can occur at probably any age, and this should not be forgotten. The response to therapy is beneficial—not cure so much as response. During the war years roentgen therapy was given, two or three doses, thirty to forty-five days apart, but the tendency now is to spread it out, with administration when the patient has symptoms requiring roentgen therapy. When the roentgen therapy has been given the first time, all of these other measures must be used. The patient must realize the possibility of severe crippling that will occur in the future if he or she does not follow the regimen. Posture is extremely important, because a person with a stiff spine that is erect and in good position is not much of a cripple, whereas a patient who has a dorsal stoop, a caved in chest, restricted chest expansion, a shuffling gait or limitations of motion in other joints, is certainly a cripple. The entire program must be entered into as the doctor directs and as outlined by Dr. Query. I am certain that the statistics on the incidence of the disease as a whole and in the sexes is incorrect. In my experience in Philadelphia, there have been closer to 5 male patients to 1 female patient than the 9 to 1 previously reported; so that early diagnosis, careful treatment and proper appreciation of any of these low back pains will save many patients from many years of pain, crippling and agony.

Dr. Richard Z. Query Jr., Charlotte, N. C.: Most American investigators feel that treatment with gold preparations if of no benefit in rheumatoid spondylitis; however, Forrestier, who popularized gold compounds for treatment of rheumatoid arthritis, expressed the opinion that it was of benefit in the treatment of this disease.

PSYCHIATRIC PROBLEMS IN A THYROID CLINIC

THEODORE LIDZ, M.D.
and
JOHN C. WHITEHORN, M.D.
Baltimore

In the clinical management of hyperthyroid conditions the psychiatrist is sometimes consulted for help in handling psychotic reactions and sometimes for advice in the management of lesser emotional disturbances. Such emergency consultations set a severe trial of the psychiatrist's clinical judgment and of his ability to cooperate helpfully with surgeons and internists. The psychiatrist often wishes that he had been consulted earlier, before the psychiatric emergency arose in such a ticklish situation, but it would not be possible to satisfy this desire, even with very cooperative clinical team work, because the emotional emergency has not infrequently appeared at the very onset of the thyroid disease. The literature on hyperthyroidism abounds with notations about emotional trauma as the apparent precipitating cause of hyperthyroidism.[1] The first description of the syndrome by Parry[2] in 1803 contained comment on the sudden fright which preceded the illness. Studies between 1920 and 1935, particularly those of Maranon,[3] Mittelman[4] and Conrad,[5] documented the frequency of such occurrence. In reports of anamnestic studies of causative factors, such emotional events are the only items which are found with considerable regularity. Yet, somehow, the possibility that emotional troubles may play an important role in the cause and course of the illness seems not to have received an appropriate amount of attention in the treatment of hyperthyroidism.

In the course of a moderate number of psychiatric experiences and observations on hyperthyroid patients, one of us (J. C. W.) had formed several general impressions, some of which seemed inconsistent: First, an acute emotional disturbance, seriously endangering the thyrotoxic patient, may be precipitated by an eager psychotherapist, enthusiastically disposed to uncover psychodynamically important material. Second, the resort to a very cautious, passive psychotherapeutic

approach may likewise precipitate dangerous emotional crises. But, third, a considerably safer and smoother emotional course seemed to be gained by a rather active and aggressive "superficial" psychotherapy. There are many psychiatric patients for whom it is a considerable advantage for the psychiatrist to be alert and prompt in grasping and evaluating the emotional implications of the current life situation and to express these evaluations not in abstract terms but in decisions on practical details. This sort of prompt decisiveness on practical details had appeared particularly to be valuable in dealing with hyperthyroid patients. This set of clinical impressions is obviously not one which is very pleasing to a psychiatrist who is deeply interested in the dynamics of psychotherapy, but it did seem to be about the way the matter shaped up, empirically. These apparently contradictory impressions might perhaps be reconciled by the supposition that these patients were in rather desperate need of some one who would show interest and consideration but would be firm and decisive in his own mind—some one who was able to take charge of a situation, but not in an offensively domineering or coercive fashion—in short, some one to depend on.

During the postwar period at the Johns Hopkins Hospital we have been developing, in close relationship with the department of medicine, a plan of regular and systematic attention to the personality functions in all the patients on a medical service, not just those acute and exaggerated personality problems for which a consultation is urgent. We have been particularly fortunate in the collaboration provided in the thyroid clinic. To have a regular part in the study and treatment of all the thyroid patients in a clinic provides a much more satisfactory basis of knowledge than just to be called for consultation in special cases.

The purpose of the present communication is to report on the psychiatric aspects of the hyperthyroid patients as seen by one of us (T. L.) during this experience.

MATERIAL AND OBSERVATIONS

A preliminary study of 15 thyrotoxic patients, which has been reported elsewhere,[6] lent convincing support to the hypothesis that emotional factors were of causative importance in hyperthyroidism, for almost all patients were found to have suffered a serious emotional crisis prior to the onset of the illness, which was critical because it struck at the core of the weakness in the personality configuration. It is not possible to present the complete observations here, but random selection of 5 cases from the current series will serve to illustrate the consistency with which emotional traumata antecede the illness. 1. A 40 year old Negro woman became ill shortly after the nephew she had raised as a son married and disappeared, at the same time that the eldest sister who had raised her was dying. 2. A patrolman who had been scrupulously conscientious was by-passed in promotions because of political influences and became hostile and somewhat paranoid toward the men on the force; he was impelled to quit, unconsciously afraid of his hostile impulses, but was unable to relinquish the security provided by his position. 3. A 45 year old woman decided to leave her alcoholic second husband who neglected her, but felt forced to return to him when she felt unwanted by her mother and her children. 4. A 40 year old childless Negro woman left the job that had been a major source of satisfaction, to keep tabs on her husband, and then felt compelled to leave him when she obtained proof of his infidelity, but was unable to leave and live alone. 5. A young woman left the aunt who had raised her when her husband returned from the Army, but could not endure the domination of her mother-in-law and considered separating from her husband to regain her aunt's oversolicitous protection when she became pregnant. These were the last 5 patients admitted to the clinic at the time of writing, rather than selected examples.

These 5 cases also serve to illustrate a characteristic meaning in the precipitating traumatic events. The trauma which preceded the onset of the illness typically involved the loss or threat of loss of a cardinal interpersonal relationship. The particular sensitivity of thyrotoxic patients to such loss seemed to be clarified by the developmental history. As a group, with due respect for the error and approximation of generalizations, they had in childhood felt less wanted than a sibling, but eventually had become the successful rival for parental affection by becoming the good child who gains affection and attention by constant giving and doing for others and had persisted in this devoted, yet dependent, pattern after the rival siblings had become emancipated. Unless they can give of themselves, they feel unwanted and rejected. They are inordinately jealous of affection and strive to gain all-embracing affection from another person by binding themselves to a parental figure, a child or a spouse by smothering oversolicitude. They expect in return the same unswerving fidelity they tendered their parents. To have their offerings rebuffed, or to become unneeded, appears to reawaken the childhood insecurities, and they become resentful and depressed.

The consistency of such observations led to the reorganization of the Thyroid Clinic of The Johns Hopkins Hospital on the basis of the hypothesis that the thyrotoxic patient presents a serious psychiatric as well as an endocrine problem. The reorganization took place at the time of the advent of n-propyl thiouracil, when an experimental study was being established to learn whether or not prolonged medical therapy could obviate surgical treatment in a substantial number of patients.[7] The shift of the major therapeutic responsibility from the surgeon to the internist, and from the ward to the outpatient department, created new problems that required psychiatric help. The patient was apt to be extremely unstable until the metabolic rate fell, and the degree of instability had to be evaluated during clinic visits both to minimize suicidal risks and to recognize when the patient was incapable of adhering to the medical regimen without hospitalization. The experimental study was broadened to attempt to evaluate the proposition that reestablishment of emotional equilibrium might be essential to the maintenance of a normal metabolic rate after discontinuance of treatment with n-propyl thiouracil. It will take several years before any conclusions can be reached, but in the meantime it has become apparent that the psychiatrist and the social worker, or at least the utilization of psychiatric insights and technics, may play an important role in the treatment program.

[6] Lidz, T.: Emotional Factors in the Etiology of Hyperthyroidism, to be published.

[7] Asper, S., and Sisson, J. H.: Use of N-Propyl Thiouracil in the Treatment of Hyperthyroidsm, to be published.

The treatment of the hyperthyroid patient has become a cooperative and closely integrated concern of the internist, the psychiatrist and the social worker. New patients are interviewed by both the psychiatrist and the social worker and the therapeutic strategy formulated by a conference of all three participants. The fruitfulness of the psychiatric participation depends on general psychiatric insights and technics for managing anxious and disturbed persons, but more specifically on the special understanding of thyrotoxic patients derived from the preliminary survey.

Although the utilization of *a priori* concepts occasionally leads to error, the constellation has only rarely fallen wide of the mark and has brought recognition of landmarks that serve to orientate the therapist rapidly and permit short cuts in treatment. For example, the few adolescent patients seen have suffered serious jealousy revolving around the separation of their parents and their rejection by one or both parents. In cases of hyperthyroidism starting during pregnancy, the patient has been found to be struggling with her need but inability to leave her husband because he has been neglectful in favor of his mother or a mistress. When the illness arises after marriage, problems are apt to revolve about difficulties in leaving the parental home and jealousy of the husband's attachment to his own family. Older patients are caught up in the loss of a child whom they have tried to attach to themselves permanently by means of smothering oversolicitude. These few examples may serve to give an impression of how the grasp of a dynamic configuration can be utilized to recognize crucial problems and to focus therapy from the early interviews. It is fairly characteristic of hyperthyroid patients to be outgoing persons who relate to others easily and who have made a workable adjustment to living despite serious flaws in their maturation. The psychotherapeutic problem consists in helping the patient to accept a basic attitude of emotional dependence and adapt it to the actual life situation. Only a minority require psychotherapy directed at a thoroughgoing modification of the personality structure.

PRACTICAL SOLUTION OF PROBLEMS

In a clinic oriented toward recognition of the importance of the immediate life situation and the personality structure, the patient realizes from the first encounter that resolution of personal problems is as much a concern of the personnel as diagnosis of symptoms and medical prescription. Either the internist or the social worker, rather than the psychiatrist, may carry the brunt of helping the patient regain emotional equilibrium. An internist who is aware of the possible precipitation of thyrotoxic illness by the loss of a key person in the patient's life may, while eliciting the initial history, pay particular heed to the passing reference to the recent death of the patient's mother; he may hold the patient's discussion to this point even though it evokes uncontrollable sobbing. The depressive concerns underneath the habitual smiles are uncovered, and the physician establishes a firm relationship by indicating his understanding of the importance of the recent death to the patient. With the advice of the psychiatrist and the assistance of the social worker, he helps the patient into new patterns of living in which she may find freedom from the hopeless longing for a maternal figure to offer security. In some cases the social worker may carry the major responsibility for personal support, as in one fairly desperate situation in which a hypomanic boy with serious psychopathic trends, who had been brutally rejected by both parents, was found a stable foster home in which he could live after his thyroidectomy.

The psychiatrist is confronted by many problems aside from the participation in the routine treatment of patients in the experimental study. Emergency situations must be met and critical decisions made. Psychotic manifestations of moderate severity, sufficient to interfere with treatment, have been present in almost 20 per cent of the patients. Although in many the psychotic difficulties disappear or recede as the metabolic rate falls, the indication of a serious personality disorder continues in others. Attention to some fairly consistent patterns helps prevent unmanageable crises. Patients verging on thyroid storm are hospitalized, of course, and psychiatric care provided. Those occasional patients with diabetes as well as hyperthyroidism have also been hospitalized, for the few seen thus far have all been psychotic. It has been found warranted to assume that persons with recurrent hyperthyroidism after thyroidectomy are struggling with serious and unresolved personality difficulties. Attention to the reasons why thyrotoxic patients oppose hospitalization and often insist on leaving too soon has helped forestall emotional crises. It has been found that it is not simply a matter of extreme restlessness associated with hyperthyroidism, but rather that many of these patients cannot relax while away from home because they seem to believe that disaster will overtake their families unless they are present to ward off danger by the magic of obsessive worrying. A knowledge of this pattern, and the liberal relaxation of visiting rules to provide fairly continuous contact with the family, have often brought a striking improvement in the patient's attitude toward hospitalization.

Attempts to utilize the psychiatrist to aid in the differential diagnosis between mild hyperthyroidism and anxiety states has proved rather pointless. The uncovering of serious neurotic traits does not weigh against, but in favor of, the presence of hyperthyroidism. The utilization of n-propyl thiouracil has diminished the need for clearcut differentiation, and, as the impression is currently held that perhaps no differentiation should be made, both medication and psychotherapy are utilized as with clearcut cases.

Whenever possible the principal psychiatric emphasis is placed on the practical solution of problems arising out of recent loss of security, dealing with them as concretely and directly as the personality structure of the patient permits. It is not possible in this brief presentation to cite examples of all the problems which arise. Perhaps foremost among the benefits of the incorporation of psychiatrist and social worker into the routine care of thyrotoxic patients has been the improved morale of the clinic. The patients respond to the highly personalized and individualized therapy by readily seeking help in managing their personal problems, as well as by the regularity of their attendance and unusually fine adherence to the regimen through the lengthy period of therapy and study.

SUMMARY

An attempt is made to describe briefly the reorganization of a thyroid clinic to cope with the emotional difficulties which are encountered in most thyrotoxic patients and which seem to play an important role in the precipitation and course of the illness. Recognition of the importance of emotional problems in the causation of hyperthyroidism is an old story. This communication reports an attempt to take this knowledge from the theoretical realm and to make it serve in the practical management of patients, utilizing it in the attempt to restore the patients to useful satisfactory living rather than concentrating simply on the restoration of the metabolic rate to within normal limits.

ABSTRACT OF DISCUSSION

Dr. F. P. Moersch, Rochester, Minn.: In spite of many references in the early literature to the emotional factors associated with hyperthyroidism, little serious attention has been given to this phase of the problem until relatively recently. One of the important points of the paper is the over-all situation in which the psychiatrist moves in with the internist in a thyroid clinic working hand in hand to the benefit of the patient and toward a higher grade of medical practice. This type of cooperation is being extended to all fields of medicine. The pattern presented by Dr. Whitehorn and Dr. Lidz is one that would be well to heed more closely. My colleagues remain in a quandary as to the causes of hyperthyroid states. They recognize that a person with hyperthyroidism "goes to pieces" quickly when confronted with emotional difficulties. After World War I and the influenza epidemic, no great increase in the number of hyperthyroid patients was noted. It is my impression that there was a steady increase in hyperthyroid cases up to about 1927. With the depression in 1930, there was observed a sharp drop in the number of hyperthyroid patients, and this decline has been sustained up to the present. I wonder whether Dr. Lidz and Dr. Whitehorn have any explanation for this fact. The psychiatric approach which the authors use appears to be a common sense approach, based on a knowledge of dynamic principles used by therapists who have the security of their knowledge and conviction. Undoubtedly, many of the hyperthyroid patients are in desperate need of help, and to a neurologist it would seem that the ministrations of a careful therapist who stands for security would be of great value in these crises. While the authors do not claim to set forth a personality profile or to state authoritatively that the conditions which they observed were the universal emotional causative factors of hyperthyroidism, their work lends credence to the fact that the type of trauma which preceded the type of illness typically involved the loss of some important interpersonal relationship. The authors confirm that it is pointless to attempt to define for the internists where hyperthyroidism stops and anxiety symptoms begin. I, too, believe that the two conditions are usually combined. The fact that the hyperthyroid clinic was so successful is a tribute to the willingness of clinicians to see the value of psychiatric aid when it is presented in a practical and an understandable manner. That the internist and the social worker, rather than the psychiatrist, should carry the brunt of helping the patient regain emotional equilibrium will be welcome news to clinicians in general. It is apparent that there will not, for a long time, be a sufficient number of psychiatrists to go around. The fact that almost 20 per cent of the patients encountered have had psychotic symptoms is testimony to the urgency of the problem and the importance of emotional factors in the disease. The hints contained in the paper regarding the liberal relaxation of visiting rules in order to provide continuous contact with the family are of great practical value in the management of thyrotoxic patients.

Dr. Therese Benedek, Chicago: I agree with the authors that the acute or threatening thyrotoxic state is usually not accessible to any active—uncovering or systematic—but long psychotherapeutic procedure. Therefore, it seems to me that it is the method of choice to treat the patient in the frame of his immediate therapeutic needs. The integration of the psychiatric aspect of this therapy, however, does not deserve to be called "superficial." The effectiveness of the approach is the result of the understanding of the presenting conflict situation and its "relationship to the core of the weakness" in the total personality. Acute thyrotoxicosis is the end result of a long intrapsychic fight, during which the patient often was an active-appearing, outgoing, doing, giving, even self-sacrificing and therefore self-satisfied person. Now, when under the onrushing danger of anxious and aggressive tension he feels that he is losing his battle, the patient becomes confused and helpless and often even desperate. Handling the case in a way which takes in account the patient's needs and sensitivities, and succeeds in establishing the patient's sense of mastery in regard to the presenting conflict situation, represents more than a little feat even for the experienced psychiatrist. Even after the metabolic rate is slowed down these patients rarely become accessible to deep psychoanalytic treatment. For the thyrotoxic patients, like children once burned by fire, remain afraid of a possible eruption of their underlying conflicts. Thus in most of the cases one will have to be satisfied if the patient's life situation will permit him to live without accumulating too much hostile and aggressive tension again. Achieving such adjustment will remain—except in the few individually treatable cases —in the hands of such team work as Dr. Whitehorn's clinic represents. The program of this meeting indicates that such team work does not need to be restricted to the thyroid clinic. No doubt the thyrotoxic state is the most apt to demonstrate the interaction between emotional and metabolic processes. The growing understanding of disease as the disturbance of the functional balance of the person as a whole—and the growing knowledge of how this balance can be best sustained and served within the family and by the community—seems to stimulate similar integration of efforts in other branches of metabolic and internal medicine.

Dr. Theodore Lidz, Baltimore: Concerning Dr. Moersch's question, I cannot say what may account for the change in incidence of hyperthyroidism. I have not heard of any clearcut decline such as he mentioned. However, it was noted that relatively little thyrotoxicosis was seen in the armed forces during the last war, whereas a fair amount was seen during World War I. Even then, Maranon pointed out, it was not as common among men in combat as among persons living at home. He expressed the belief that this was as might be anticipated because acute trauma is not as important as problems involving persons intimately related to the patient. I do not know of any definite figures concerning the incidence of hyperthyroidism among the civilian population during the last war, but, even if there were, so many factors are involved that it would be extremely difficult to analyze them. Dr. Moersch indicated that we believe an internist can carry the brunt of therapy. We did not wish to intimate this. We would like to believe that the internist could carry the brunt of therapy, and we hope that some day he will be able to do so. At present he leaves the more complicated situations to the psychiatrist, though he manages to carry a fair number of patients himself. I was happy that Dr. Benedek made two comments in particular: that this type of treatment, though brief, is not superficial and that it does not have to be confined to a thyroid clinic. Actually, we were trying to illustrate how therapy can be brief and effective in conditions in which we believe we have a fairly good working hypothesis of the dynamics of the personality structure. Other persons might feel that they could handle patients with peptic ulcer or hypertension more readily. We decided to use the thyroid clinic to endeavor to work out and demonstrate the benefits to be derived from the integrated activity of internist and psychiatrist because we thought that we could size up the problems rapidly, start therapy immediately and be able to demonstrate some tangible evidence of the

POLYPOID LESIONS OF THE TERMINAL PORTION OF THE COLON

With Special Relationship to Fulguration

LOUIS A. BUIE, M.D.
NEWTON D. SMITH, M.D.
RAYMOND J. JACKMAN, M.D.
and
JOHN R. HILL, M.D.
Rochester, Minn.

Knowledge of the pathologic manifestations and of the diagnosis of polypoid disease of the colon has progressed, but results of treatment of the condition still are discouraging. Herein fulguration (which we define as a nonsurgical procedure) is described and reasons for its use are given. Also, how the proctologist can aid in combating this grave disease is outlined.

Polyps may occur singly or in numbers, and they may be sessile or pedunculated. The entire colon may be involved by polypoid disease; there are grossly two types of this condition. In one type, the polyps are discrete and gross evidence of pathologic change in the intervening tissues is absent. In the other type, there is a diffuse hyperplastic involvement, which may be segmental or total, and many polyps of all types, sizes and shapes are found. Often, no part of the wall of the colon is free from disease. Such complete involvement is important and must be evaluated in relation to treatment.

MATERIAL

In this paper, we are dealing with material in which the number of polyps per case generally was one or two and never was more than ten unless we make clear that we are writing of multiple polypoid disease. We examined the records of 1,640 patients, proctoscopic examination of whom had revealed polypoid disease of the terminal portion of the colon (table 1). These patients first registered at the Mayo Clinic in the years 1935 to 1937, inclusive; however, discovery of a polypoid lesion in the terminal portion of the colon may not have been made until a subsequent visit. Consequently, an accurate estimate of the incidence of polypoid disease cannot be made from this study. Although the records of 1,640 patients were studied, detailed consideration was given to only 1,402. In 238, notation of complicating factors was found; these cases will be discussed later. Of the 1,402 patients whose records were used for special study, 1,287 were subjected to fulguration. These 1,402 cases were arranged in three groups. A patient was put into one or another group on the basis of the opinion concerning his suitability for fulguration, as recorded by the examining proctologist before treatment, not on the basis of his suitability for fulguration as demonstrated when the results of treatment finally were assessed.

CATEGORIES

Group 1.—This group included 1,345 patients for whom fulguration was considered to be the best treatment. However, for reasons which will be explained later, 105 patients received either surgical treatment or no treatment (table 2). Thus, 1,240 patients were treated by fulguration. In 23 of these 1,240 instances, lesions were large and radium also was applied in small topical doses in order to prevent hemorrhage.

When more than one polyp was discovered, the size of only the largest was recorded. The diameter of the lesions in cases of group 1 ranged from 1 mm. to 5 cm. inclusive. In 74 per cent of the 1,240 cases, the diameter of the polyps was less than 1 cm.; in 23 per cent, it was 1 cm. or more but less than 3 cm., and in 3 per cent it was from 3 to 5 cm. inclusive. In 14 cases, the diameter of the polyps was greater than 4 cm. In 9 of these 14 cases the polyps were pedunculated, and in 5 they were sessile. The diameter of one pedunculated polyp was 5 cm. In 752 cases (60 per cent of the 1,240), one or more of the polyps were fulgurated at the time of the initial proctoscopic examination. This was the rule when the diameter of the polyps was 5 to 6 mm. or less. In the remaining 40 per cent of the 1,240 cases fulguration was performed later. In this group of 1,240 cases were several in each of which a pedunculated polyp was situated orad to the level usually seen in routine proctoscopic examination. The presence of some of these polyps was suspected because blood or bloody mucus appeared in the sigmoid in the course of proctoscopy, and they were discovered when a longer instrument was used. In each of several other cases, when routine proctoscopic examination failed to reveal the polyp, it was discovered by the roentgenologist and, when the patient returned for more thorough proctoscopic examination, the proctologist was able to discover a lesion which often was situated as much as 45 cm. proximal to the anus.

In a few instances in which the lesion was situated near the anorectal junction, caudosacral anesthesia was used in order to prevent pain during fulguration. Otherwise, anesthesia was not employed.

Seventy-seven per cent of the lesions were situated in the proximal half of the rectum and in that portion of the sigmoid which can be visualized through the sigmoidoscope. Small lesions (usually less than 1 cm. in diameter) were fulgurated regardless of their situa-

* Treatment surgical, 14 patients; no treatment, 91 patients.

From the Section on [illegible] Mayo Clinic, Rochester, Minn.
Read before the Sect[illegible], and Proctology at the Ninety-Seventh Annual [illegible]an Medical Association, Chicago, June 24, 1948.

tion in the bowel. Larger sessile lesions were fulgurated only if they were situated in that portion of the bowel which was thought to be distal to the level of the peritoneal reflection. All pedunculated lesions were fulgurated, without regard for their situation in the bowel, if adequate exposure could be obtained.

As has been said, in 105 cases of group 1, either treatment was surgical or no treatment was given. In 14 of these 105 cases (table 2) lesions were situated near the anus, where they could be exposed satisfactorily, and local surgical excision was performed. The problem of selecting cases in which fulguration is applicable will be discussed in subsequent paragraphs. In 91 instances (table 2) no treatment of the polyps was administered. Fulguration was recommended in all of these cases, but, for various reasons, it was not accomplished. In most of these cases treatment was withheld because the patient was seriously ill from some other disease. In a few cases the patient either refused to accept treatment or went home in order to obtain treatment there.

We do not propose to discuss the histologic structure of polypoid lesions. It should be recorded, nevertheless, that of those cases of group 1 in which the lesion was subjected to biopsy, in none was the degree of malignancy greater than grade 1 (Broders' method). Most lesions were either adenomas or adenocarcinomas of low grade 1 in adenomas. In the latter, malignant change of low grade was observed at the periphery of the polyp. Examination by a pathologist was not made in many cases of this group. The physical characteristics of the lesion (size, mobility, consistency, situation in the bowel and whether or not it has a pedicle) are as significant clinically as the cellular structure, and usually the decision as to applicability of fulguration was reached before the microscopic diagnosis was known.

Group 2.—This group was composed of patients for whose condition fulguration, although not the best treatment, was considered, for one or another reason, to be justifiable. For example, the lesion may have been situated a little high or it may have occupied an unfavorable position on a lateral wall, or on the anterior wall, of the bowel, or it may have been a little large or difficult to expose. Ordinarily such a lesion would not be treated by fulguration. In some cases, however, the patient either was unwilling to submit to a surgical operation or he was physically unfit for it; hence fulguration was performed. On the other hand, although fulguration was considered at least justifiable in this group of cases, for one reason or another it was not always performed. Thus, 10 of the 49 patients in this group were treated surgically (table 3). It should be said here that teamwork of internist, general surgeon and proctologist is especially important when cases of this group are being considered. In 23 (14 plus 7 plus 2, table 3) of the 39 remaining cases in group 2 in which treatment was by fulguration (or fulguration plus radium), the lesion was definitely malignant and in 15 of the remaining 16 cases (1 plus 15, table 3) there were adenocarcinomatous changes, grade 1, in basically adenomatous lesions. The lesions varied from some which were about 1.5 cm. in diameter to others which involved almost the entire rectum.

The lesions were divided into three categories: (1) small—those which were less than 2 cm. in diameter; (2) medium—those which were 2 cm. or more but less than 4 cm. in diameter, and (3) large—those which were 4 cm. or more in diameter.

In 9 cases (7 plus 2, table 3) microscopic examination revealed malignancy of grade 2 or 3. In only 1 of these 9 cases was the lesion 4 cm. or more in diameter. In general then, the grade of malignancy of the small lesions was higher than that of the large lesions. The pathologist's diagnoses were made at biopsy. If serial sections of all growths could have been made, a higher degree of malignancy might have been discovered. In the group of cases in which the lesions were large, the polypoid disease frequently occurred in conjunction with, and as a part of, diffuse hyperplasia of the mucous membrane.

Among the 39 patients of group 2 who were treated by fulguration, the lesions of 5 were pedunculated. We have said that all pedunculated lesions were fulgurated, regardless of their location. Therefore, speculation might arise as to why these growths were not included in group 1. The reason is that in these 5 instances the lesions, which were situated in the sigmoid, were extremely difficult to expose. In fact, in 1 case, three unsuccessful attempts were made to fulgurate a sigmoidal lesion. It was seen on two occasions, but the attachment of the pedicle could not be exposed and it was decided that the lesion could be removed more safely by transcolonic excision. However, when this was attempted, the surgeon was unable to discover the polyp, which was only 1.5 cm. in diameter, and, finally it was fulgurated despite the fact that the site of attachment of the pedicle never was visualized. Proctoscopic and roentgenologic reexamination made one year later gave negative results. Only in rare instances should a pedunculated lesion be fulgurated unless the entire pedicle is visible. This attitude

* Treatment surgical, 10 patients

is maintained for two reasons: First, there may be polypoid tissue at the base of the pedicle, and, second, grave difficulties may arise if hemorrhage should occur. In another case a portion of a pedunculated sigmoidal polyp was fulgurated, but, before fulguration could be completed, the polyp vanished beyond the reach of the sigmoidoscope. Repeated unsuccessful attempts were made to reach the polyp through the sigmoidoscope, and finally it had to be removed transcolonically.

In the sigmoid in each of 2 cases was a sessile lesion which was treated by fulguration and by radium. Each lesion involved the posterior wall at a point 14 cm. internal to the anus. Biopsy of one lesion revealed colloid adenocarcinoma, grade 3, in a growth which was 1.5 cm. in diameter. Biopsy of the other lesion disclosed adenocarcinoma, grade 2, in a growth which measured 3 by 3 cm. The patient in examination of whom the smaller of these two lesions was discovered was examined seven years after the treatment was finished, and no evidence of disease of the bowel was discovered. The patient who harbored the larger lesion remained well, and there was no evidence of malignancy twelve years after conclusion of the treatment. The lesions of these 2 patients were not of a type which usually should be treated by a combination of fulguration and radium. Later in this paper, it will be evident that such treatment of some lesions gave a poor result even though they were situated more favorably than were the two just described and were believed to be suitable for this type of treatment. Our experience with the 2 patients just mentioned demonstrates that in some cases in which fulguration is not the suitable treatment, but in which surgical operation is contraindicated, hope need not be abandoned.

In 28 of the 39 cases in which patients were treated by fulguration, radium also was used. In most of these cases radium was employed only as a precaution against hemorrhage and was applied to the charred mass of fulgurated tissue immediately after completion of fulguration. In such instances, 50 mg. of radium was inserted and was allowed to remain in place for three to four hours. In a few instances in which difficulty was encountered in eradicating the lesion by fulguration, radium was used in larger doses, more frequently, and for longer periods.

Group 3.—This group included patients who received fulguration for its palliative effect only. There were 8 patients in this category, and they were included in this group for the following reasons: 1. Two patients had advanced annular carcinoma, and fulguration was used in an endeavor to maintain the lumen of the bowel and thus prevent obstruction. 2. Four patients had operable lesions, but radical surgical measures were contraindicated because of complicating diseases; fulguration was not expected to effect cure. 3. Two patients had operable lesions, but each refused to permit a radical procedure. In such cases fulguration offers little hope of cure, and the patients accepted it as a palliative procedure.

Concomitant Disease.—Now we shall consider the records of the 238 patients who could not be included in the three main groups because conditions of the colon other than the presence of polyps made evaluation of the results of fulguration difficult.

Chronic Ulcerative Colitis: Eighty-two patients (5 per cent of the entire series of 1,640 whose records were examined) were afflicted with chronic ulcerative colitis, and polypoid disease occurred as a complication. When this combination existed, the ulcerative process usually demanded primary consideration. Fulguration was employed to destroy polyps which could be reached through the proctoscope in 42 of the 82 cases (51 per cent). Forty of the 82 patients could not be treated by fulguration, either because the chronic ulcerative colitis was so active that treatment by fulguration was considered hazardous or because contraction of the lumen of the bowel rendered fulguration impossible. Several of the 82 patients had so-called pseudopolyps or inflammatory polyps. In 72 per cent of the cases complicated by chronic ulcerative colitis the polyps were multiple. Most of the 82 patients were examined periodically for years, and study of their records proved that although new polyps were prone to occur at other sites, polyps were not found where the original lesions had been destroyed. In some instances, of course, as is true also in cases of "multiple polyposis," the original lesions were numerous and, consequently, whether new lesions occupied the site of old lesions could not be ascertained. In such cases, frequent examinations and treatment over a period of several months were necessary in order to control the polypoid disease.

Multiple Polypoid Disease: Thirty-two patients (2 per cent of the entire series of 1,640) suffered from "multiple polyposis," a condition which probably should be termed "multiple polypoid disease of the entire colon." Extensive investigation of the family histories of these patients was not made, but in almost every instance some relative had suffered from a similar condition.

Treatment for the multiple polypoid disease which affected the 32 patients was destruction by fulguration of the polyps in that portion of the colon which could be reached through the proctoscope and removal of that part of the colon which was not thus accessible. At present, we believe that ileosigmoidostomy and colectomy should be performed first and fulguration second. This sequence is preferred because of the risk which attends colectomy. Fulguration may have to be carried out periodically for several months in order to destroy all of the polyps accessible through the proctoscope. To complete all such work, only to see the patient succumb after surgical operation, would be doubly unfortunate. Reexaminations often are necessary for years in order to eradicate the small new polyps which grow in practically all of these cases.

Grossly there are two types of multiple polypoid disease of the colon. In one, the polyps are discrete and the mucous membrane between them appears, grossly, to be uninvolved. In these cases, fulguration can be carried out unless that portion of the bowel to be cleared by fulguration is the site of malignant growth. In the other type, there is a diffuse hyperplastic involvement of the mucous membrane associated with the polyps; thus fulguration usually is not feasible, because the substance of the wall of the bowel must be destroyed in the course of the fulguration and the terminal remnant consequently becomes a useless, scarred and contracted tube. In this group of 32 cases, fulguration of the polyps in the terminal segment of the colon was accomplished successfully in 18 of 19 cases in which it was attempted. In the case in which our effort was unsuccessful, adenocarcinoma grade 2 developed in the rectum and combined abdominoperineal resection was necessary. By "successfully accomplished" we mean that the polypoid disease in the terminal portion of the colon was destroyed and that polyps were not found when the patient was last examined. In 13 of the 32 cases fulguration was not performed. Several patients refused treatment; some preferred to have treatment at home, and in 8 cases fulguration was not considered feasible for reasons too obscure to be evaluated here.

Carcinoma: The remaining 124 patients (8 per cent of the total series of 1,640) had polyps, but they also had carcinomas of the same or different portions of the colon. It should be mentioned that the incidence of 8 per cent of associated malignant lesions is not accurate, because there were some patients in the "multiple polyposis" group and in group 2 who had carcinomas. The malignant lesions were treated by surgical methods, and in some instances polyps were removed with the resected portion of bowel. Those polyps which were not removed in this manner were fulgurated either by way of the rectum or through the colonic stoma. In several instances, polyps were found during a "three way" examination which was performed in an endeavor to determine whether or not a colonic stoma could be closed. During a three way examination, the rectum and a portion of the sigmoid are examined in the usual manner and those portions of the colon which lie proximal and distal to the colonic stoma are examined through this opening into the colon.

SEX; AGE; TYPE, NUMBER AND SITUATION OF POLYPS

Although this paper relates primarily to treatment, some numerical data have been recorded for the entire series of 1,640 cases. Sixty-one per cent of the patients were male and 39 per cent female (a ratio of approximately 3:2). Eighteen per cent of the patients were less than 40 years of age, and 6 per cent were less than 30. The youngest patient was 1 year old and the oldest 82. Seventy-six per cent were between the ages of 30 and 70 years. Sessile lesions occurred three times as often as pedunculated lesions. Often both types of polyps were discovered in the same case. Seventy-four per cent of the patients had single lesions, and 26 per cent had more than one.

Excluding those patients who had polyps in both rectum and sigmoid, 56 per cent of the lesions were found in the rectum and 44 per cent in the sigmoid. In order to make this determination, the rectum was arbitrarily considered to extend 12 cm. internal to the inner margin of the anus. Seventy-seven per cent of the lesions were situated proximal to the middle part of the rectum (about 6 cm. internal to the pectinate line). Except in group 2, in which lesions were relatively large, the wall on which the polyp was situated was not considered significant. In a previous communication, however, one of us has shown that approximately 40 per cent of single lesions occur on the anterior wall.

RESULTS

We urge periodic examination of all patients who have had polypoid lesions of the terminal portion of the colon. The frequency of examinations depends on the seriousness of the condition. Roughly speaking, examination one to three months after completion of treatment is urged for all patients whose lesions were 1 cm. or more in diameter. There is more need for the examination if the lesion was sessile than if it was pedunculated. Often, if the original lesions were large, fulguration of tiny residual portions of polypoid tissue is required several times, at intervals of a few weeks following the first fulguration. The reason for this is that edema develops contiguous to the site of fulguration and, because of this and the spastic activity of the wall of the bowel, the physician is unable to destroy all of the polypoid tissue. When four to six weeks have passed since the original fulguration, the edema usually has subsided and all polypoid tissue can be recognized easily and treated. After that, depending on the observations at the first reexamination, a second reexamination, a month to a year later, usually is recommended. Regardless of the size of the lesion, we do not recommend deferring examination longer than a year. When this paper was written, several patients of the series still were returning annually for reexamination, despite the fact that many years had elapsed since evidence of their disease last had been discovered, so thoroughly had they been impressed with the importance of reexamination. Roentgenologic examination of the colon never should be overlooked in cases in which polyps are found in the course of proctoscopic examination.

In the series of cases on which this paper is based, the plan of reexamination which has been described was followed, not only so that the site of the original lesion might be reexamined but also so that search for new polyps could be made. For our study of results we employed only that information which had been obtained by examination of patients after the lapse of at least six months following treatment. The records of 502 (39 per cent) of the 1,287 patients of groups 1, 2 and 3 who had been treated by fulguration fulfilled this requirement.

In 111 (22 per cent) of the 502 cases, new polyps were found in places which had not been the sites of the original lesions. The results of treatment in the three groups varied considerably, as would be expected. Hence, each group will be discussed separately.

Group 1.—Of group 1, which included those patients for whom fulguration was considered to be the best treatment, 457 of the 1,240 who actually were treated by fulguration were reexamined at least six months following completion of the treatment. The condition of 427 (93 per cent of the 457) was followed for at least a year, and that of 176 (38 per cent of the 457) was observed for five years or more. The longest period was twelve years. Among patients who were examined periodically for five years or longer, it was not unusual for ten to fifteen examinations to be performed.

In only 3 instances did we discover what we believed to be a lesion at the site of an original polyp. Of these 3 cases only 2 are included in a significant part of table 2, for a reason that will be given in the brief report of the third of the 3 cases.

One of the patients was a woman, 60 years of age, who originally had a sessile lesion 2 cm. in diameter on the lateral wall of the upper part of the rectum. Biopsy revealed "grade 1 adenocarcinoma in an adenoma." The first fulguration was performed in July 1936, and, in addition, a small dose of radium was applied. The patient returned four months later, and a polypoid lesion 7 mm. in diameter was discovered at the site of the original lesion. This was fulgurated, and the patient was advised to return in three months for examination. However, she did not return until October 1940, four years later, and again there was a polypoid lesion, 1 cm. in diameter, at the original site. This was fulgurated, and again an attempt was made to impress the patient with the need for frequent reexamination. At the time of the writing of this paper, however (1948), she had not returned. Nevertheless, the physician who referred the patient to us, when responding to our letter of inquiry, stated that the patient was alive in April 1948 and that his examinations of the patient's rectum had not revealed any evidence of disease.

The other patient of the 2, a woman 45 years of age, originally had three "large proliferating masses" in the upper portion of the rectum. The lesions involved all walls of the bowel, and biopsy revealed "low grade 1 adenocarcinoma in an adenoma." The patient was subjected to fulguration periodically for two months (December 1935 to February 1936), and finally the lesions were destroyed. A topical dose of radium was applied on one occasion because of the fear of hemorrhage. During the following four and a half years, small polypoid lesions were fulgurated on five different occasions at, or near, the sites of previously treated polyps. The date of the last treatment was October 1940. Thereafter the patient was examined on numerous occasions and no further polypoid tissue was found. The last examination was made in April 1947.

The latter patient of the 2 whose cases have just been reported required repeated treatment over a period of almost five years, after which the bowel was free of polypoid disease for seven years. She had lesions which were not the most favorable type for treatment by fulguration and which usually are included in group 2. In this instance, however, the proctologist felt that fulguration should be employed, probably because of his desire, and that of the patient, to save the rectum. It is doubtful that his opinion would be the same today, for we have learned from experience that some of the greatest difficulties are encountered while attempting to eradicate by fulguration lesions of this type.

The record of 1 other patient which was included in group 1 is worthy of review.

The patient was a man, 46 years of age, who had a movable sessile lesion, 4 cm. in diameter, on a lateral wall of the middle portion of the rectum. Biopsy revealed that the lesion was an "adenoma." It was fulgurated, and a topical dose of radium was applied. The patient returned for reexamination three months later, and there was an indurated ulcer at the site of the previous lesion. More tissue was secured for microscopic examination, and the pathologist reported "grade 1 adenocarcinoma." A combined abdominoperineal operation was performed. When the removed specimen was examined, malignant or adenomatous tissue could not be found. Was all the malignant tissue removed when the specimen was taken for microscopic examination? Ten years later the patient returned, and evidence of disease was not found. This patient was not included in that part of table 2 which has to do with reexamination because six months had not elapsed following treatment.

Group 2.—The borderline cases which we included in group 2 have been most perplexing to us. Fortunately, they comprised only a small portion, 49 cases (3 per cent) of the series of 1,640 cases. The results of treatment of these patients have not been inspiring.

Opportunity was afforded to reexamine all of the 39 treated patients in this group of 49 for at least six months after the original treatment was concluded. Thirty-five of the patients were reexamined for periods of one year or longer; 14 of these 35 were reexamined for periods of five years or longer, and a few were still returning periodically when this article was being written (1948). The first treatment of some was given as long before the writing of this article as thirteen years.

In 28 of the 39 cases in which treatment was given, new polypoid tissue did not develop at the site of the original lesion. In the 11 remaining cases the result was not so fortunate. In 4 of the 11 cases new lesions developed at the original site of treatment, and in 7 of the 11 it was never possible to eradicate the lesions completely. The 11 cases in which difficulty was encountered were not the same as the 11 in which treatment had been by fulguration only (table 3). In fact, in only 2 cases of the 11 in which treatment had been exclusively by fulguration did difficulty arise.

Of 4 patients (table 3) whose original lesions were less than 2 cm. in diameter, reexamination of 3 gave negative results, one year, four years and seven years, respectively, after treatment. The third of the 3 patients just mentioned had had a colloid adenocarcinoma, grade 3, in the lower portion of the sigmoid. This patient was mentioned in the next to the last paragraph in that description of group 2 which was given under the general heading "Categories." The second of the 3 patients just mentioned had had an adenocarcinoma, grade 2, measuring 1 cm. in diameter on the posterior wall of the middle portion of the rectum, the ideal situation for fulguration. Concerning the first of the 3 patients just mentioned there is nothing significant to report. The fourth patient of the group of 4, however, originally had three polypoid lesions, each less than 2 cm. in diameter, on the posterior wall of the middle part of the rectum. The largest measured 1.5 cm. in diameter, and microscopic examination revealed "grade 1 adenocarcinoma in an adenoma." The mucosa between the lesions was hyperplastic, and consequently the entire area required fulguration. At the time of writing of this article, this patient had returned every three months for observation. The original treatment was administered in 1944. On three subsequent occasions, fulguration was applied to small portions of polypoid tissue which had developed at the margin of the scars when the areas had healed after previous treatment. For the six months before this report was compiled there had been no new development of polypoid tissue.

Nineteen patients (table 3) had original lesions which were more than 2 cm. and less than 4 cm. in diameter. Reexamination of 15 of these patients gave negative results six months to twelve years after treatment. Eleven of the 15 were reexamined periodically for two years or longer. Difficulty was encountered in the remaining 4 of the 15 cases. Of these 4 patients, 3 had adenocarcinomas, grade 2, and one had an adenocarcinoma, grade 1, at the time of the first examination. A short review of our experience with each of these 4 patients is appropriate.

One, who was a man 47 years of age, originally had a freely movable lesion, measuring 2 by 3 cm., on a lateral wall of the upper portion of the rectum. It was an adenocarcinoma, grade 2. The condition was treated intensively by fulguration, and much radium was applied for nine months, but the lesion was never eradicated. Finally, colostomy was performed, and this was followed by radical posterior resection. The resection was performed with great difficulty, and probably all of the malignant tissue was not removed, because the lesion recurred, or persisted, and the patient died twenty-one months after treatment had been begun.

In retrospect, it seems probable that the lesion in this case should not have been fulgurated. At first, however, the patient refused to accept the radical surgical treatment which was offered him, and we were obliged to employ the only method of treatment which he would accept.

This sort of complication brings up an interesting question concerning fulguration. If a patient is in condition to undergo a major surgical operation which he needs, but he refuses to accept such treatment, how far should the physician go in an attempt to substitute fulguration? Certainly fulguration should not be discussed until all attempts to convince the patient of the error of his decision have failed. If fulguration is to be tried, the patient should be made to understand that it may fail, and he should agree in advance that if it does fail he will accept the proper radical surgical treatment. After fulguration is begun, it is important to know how soon it can be recognized that the method will or will not produce the desired result. As a rule, it should be possible, if the lesion is single, to make this decision within eight to ten weeks after the entire growth has been fulgurated. If the result is going to be favorable, the ulcerated area, which replaces the lesion which has been fulgurated, soon should show evidence of healing and the adjacent tissues soon should become pliable, soft, movable and present a healthy appearance. If, after eight to ten weeks have elapsed, malignant tissue is still present, if the patient complains of pain, or if there is induration, immobility or other evidence that progress is unsatisfactory, then radical operation should be performed. Continuance of fulguration after such conditions have been discovered avails little, and often a prolonged course of fulguration produces perirectal inflammation and adhesions which make it difficult, if not impossible, to dissect the rectum free from the bladder, vagina or other pelvic structures when resection is attempted.

The second patient was a woman 63 years of age, who had a recurring adenocarcinoma, grade 1, of a lateral wall of the upper portion of the rectum. The lesion measured 1.5 by 3 cm. The woman had been treated by means of radon seeds by her home physician because she had refused colostomy. We found that she had gout and renal insufficiency. One of us treated the lesion by fulguration periodically for nineteen months, but it never was controlled and an obstructive mass developed despite our effort. One year after she had come to us she submitted to colostomy. That was in June 1943, and our record indicated that, as this report was being prepared, she was still alive. Evidently the colostomy was performed as a palliative procedure. Is it possible that radon seeds and fulguration could have inactivated the malignant process?

The third patient, a woman 75 years of age, had a growth in the sigmoid. She was accepted for fulguration because of her age and because the lesion, which was an adenocarcinoma, grade 2, had a very short pedicle. Fulguration had to be discontinued because of "rather profuse bleeding," and the lesion finally was removed transcolonically. The patient was well nine years after the surgical operation.

The fourth patient concerning whom difficulty arose was a man, 56 years of age, who had an adenocarcinoma, grade 2, 3 cm. in diameter, on the anterior wall of the upper portion of the rectum. This patient was accepted for fulguration because he wished to avoid colostomy. After the first course of fulguration had been completed, he was advised to return for reexamination in three months. He did not return until five years later, when we discovered an annular constricting lesion in the rectosigmoidal region. He again refused operation and died a year later; six years after the original lesion had been treated. Obviously, this lesion grew very slowly, and one might wonder whether it could have been eradicated if the patient had cooperated.

Sixteen patients (table 3) originally had lesions 4 cm. or more in diameter. Ten of the 16 patients were examined at intervals for periods which varied from six months to nine years. In 7 of the 10 cases, the shortest period of observation was two years. The final proctoscopic examination of these 10 patients revealed no disease.

In the remaining 6 of the 16 cases results were disappointing. In 3 of these 6 cases, biopsy revealed adenocarcinomatous changes, grade 1, in basically adenomatous lesions; in 2, adenocarcinoma, grade 1, and in 1, adenocarcinoma, grade 2. The smallest lesion discovered at original examination of these 6 patients involved the posterior half of the rectum for a distance of 8 cm., and in 2 of the 6 cases the growth involved about three fourths of the entire rectal wall. All lesions in the 6 cases were soft and freely movable. In 4 of the 6 instances the lesions were never brought under complete control, and in 2 they were brought under control only after three and four years, respectively, of extensive treatment. In all 6 cases strictures of the rectum developed; in addition, a rectovaginal fistula developed in 1 of the 6 cases and abscesses in 2 of them. All 6 patients were treated extensively by fulguration, and radium was administered. Of 3 patients of the 6 in whose cases biopsy revealed "grade 1 adenocarcinoma in an adenoma," 2 lived for six years and the other lived for seven years after treatment had been begun. Of 2 patients of the 6, in examination of whom adenocarcinoma, grade 1, was found, one lived four years; the other was living four years after treatment had been begun but thereafter did not appear for reexamination. One patient of the 6, examination of whose lesion revealed adenocarcinoma, grade 2, lived only one year after treatment had been begun. This patient originally had several polypoid lesions in the rectum and some higher in the colon, but his general condition at no time during treatment permitted radical surgical operation, which otherwise would have been the procedure of choice.

We have said that 16 patients originally had lesions 4 cm. or more in diameter and that examination of 10 of the 16 at periods varying from six months to nine years gave negative results. Massive or disseminated involvement of the bowel was found at original examination of only 2 of these 10 patients. In the other 8 cases of the 10, the lesions, which were discrete, averaged 4 to 5 cm. in diameter, and there was no evidence of hyperplasia of the adjacent mucosa. Biopsy of the lesions in these 10 cases disclosed a degree of malignancy comparable to that which was discovered in all but 1 of the 6 cases in which results were disappointing. In 2 of the 10 cases the lesions involved the posterior wall only.

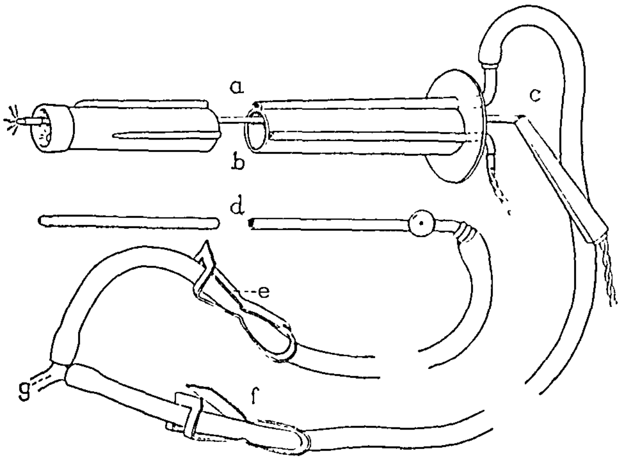
Group 3.—This was the group of 8 cases in which fulguration was administered only as a palliative measure. Results were more favorable than had been expected.

Two patients, men, 75 and 77 years of age, respectively, had annular fixed lesions in the upper portion of the rectum; these lesions were treated by fulguration and application of radium in an attempt to preserve adequate lumens. One of the 2 patients died one year following completion of treatment; the other was living nine years after treatment had been concluded, when proctoscopic examination revealed no gross evidence of regrowth of the lesion. This patient was examined frequently during the nine year period of observation, and small portions of polypoid tissue were fulgurated on several occasions. Biopsy revealed adenocarcinoma, grade 2, in both of these cases.

The remaining 6 patients (of the 8), who appeared to have operable lesions, were not operated on, either because they refused to accept radical surgical measures or because concomitant disease contraindicated radical surgical operation; all had adenocarcinomas of the rectum, grade 1 or grade 2. One of these, a woman 56 years of age, had an infiltrating lesion, grade 2, 6 cm. in diameter, on a lateral wall of the upper portion of the rectum. Her lesion appeared to be under control ten months after fulguration, but she died two months later, of coronary occlusion. The lesions of the 5 other patients of the 6 could not be controlled by fulguration and radium: 2 died within one year after this treatment had begun; 1 lived eight years; another was alive two years after treatment but was failing rapidly; the fifth was not seen after the treatment ended.

THE PROPER ATTITUDE CONCERNING FULGURATION

Fulguration plays an important part in the treatment of polypoid disease of the terminal portion of the colon but much care must be exercised in determining when it should be employed. In some instances, a lesion may possess characteristics which are favorable for fulguration, yet to employ it may be unwise or even hazardous because of other characteristics which are unfavorable.



Fulgurating proctoscope with suction apparatus: *a*, suction tube for smoke; *b*, tube for light carrier; *c*, fulgurating electrode; *d*, suction tube for liquid; *e* and *f*, clamps on rubber tubing to permit aspiration of either smoke or liquid; *g*, glass connection with source of suction.

We shall consider six factors which deserve attention while attempting to arrive at this decision:

Size of the Lesion.—Small sessile lesions can be fulgurated with little regard to their position in the bowel, and frequently we fulgurate them at the time of the original proctoscopic examination. What is meant by "small lesions?" No specific measurement can or should be laid down in answer to this question. However, if it is agreed that special care must be exercised while fulgurating lesions in the mobile portion of the sigmoid, where too much destruction of the wall of the bowel might result in perforation into the peritoneal cavity, it can be stated that sessile lesions of a diameter as great as 6 mm., or possibly 8 mm., may be fulgurated, even in that area. Of course, larger sessile lesions may be fulgurated if they occupy positions where fulguration can be performed thoroughly without danger (for example, the posterior wall of the lower two thirds of the rectum). A lesion which has a well defined pedicle may be fulgurated regardless of size or situation, provided that adequate exposure of the polyp and of the entire pedicle is obtainable. In group 1, which included patients for whom fulguration was considered the best treatment, there were only 5 patients in examination of whom sessile lesions 4 cm. or more in diameter were discovered. Cases in which lesions were large and disseminated, and cases in which large areas of the rectal mucosa were hyperplastic, were those in which the most trouble was encountered. Even in cases wherein it seemed that we had brought the lesions under control, after several years of treatment, strictures always developed. Although disseminated lesions usually are adenomatous, or of low grade of malignancy, and although they tend to remain in situ for long periods without undergoing metastasis, experience has taught us that they should be treated surgically. The expense, the prolonged period of treatment and the amount of disability which persists after treatment attest to the fact that in these cases fulguration is not the method of choice. On the other hand, lesions which may be just as large, as far as cubic content is concerned, but which do not extend over so much of the bowel wall, may be fulgurated successfully.

Situation of Lesion.—Fulguration is best applied to lesions which lie caudad to the peritoneal reflection. There is great variation in the location of the peritoneal reflection. The posterior wall of the rectum is covered by peritoneum to a less extent than the lateral and anterior walls. When dealing with lesions which involve the anterior wall, it is necessary constantly to bear in mind the proximity of the vagina, the uterus, the urinary bladder, the seminal vesicles and the prostate gland. The ideal location of a polypoid lesion, as far as fulguration is concerned, is the posterior wall of the middle portion of the rectum or the lower part of the rectum. Few lesions are so ideally situated.

Consistency of Lesion.—The softness or firmness of a lesion can be ascertained by palpation and, even when it cannot be reached with the examining finger, almost as much can be learned by "palpating" the growth with the proctoscope. The least degree of firmness should warn the examiner that there is a greater likelihood that malignancy is present.

Mobility of Lesion.—Lesions which are favorable for fulguration must be freely movable. Any limitation of mobility indicates that infiltration into the deeper coats of the bowel has begun.

Condition of Mucosa Which Is Contiguous to Lesion.—While hyperplasia of the mucosa adjacent to a small polyp probably is of no great significance, and would not contraindicate fulguration, it should serve as a warning that new lesions are likelier to occur and that careful observation is necessary.

Microscopic Examination and its Implications.—Benign polyps (adenomas) should be fulgurated if they are favorably situated and are of suitable size and shape. Malignant transformation in adenomas can be detected by experienced pathologists, and in such cases the grade of malignancy is seldom more than 1. Careful biopsy rarely should fail to reveal such malignant change, because it occurs first in the periphery of the lesion. When malignancy has been detected, it is necessary to weigh it together with all clinical factors. If the latter are favorable, in many such cases the less severe procedure, fulguration, is not only justifiable but preferable.

If the clinical factors are not favorable, some surgical procedure becomes necessary, regardless of the pathologic content of the lesion. For adenocarcinomas which apparently do not have their origin in adenomas, surgical operation is always the treatment of choice. However, if the patient will not accept such treatment or if his condition will not permit it, fulguration with or without radium should be considered. It should be reiterated that fulguration should not be discussed until all attempts to convince the patient of the error of his decision have failed.

TECHNIC OF FULGURATION

The term "fulguration," as we employ it, designates a procedure intended to destroy a growth by means of an electric spark which emanates from the electrode of a monopolar (Oudin) current. A bipolar current may be used. While a lesion is being fulgurated, the tip of the electrode should be held so that the spark will leap approximately 5 to 6 mm. from the electrode to the surface of the growth. In this manner, the superficial layers of the polyp are first dried and later charred. Soon, an actual flame extends between the tip of the electrode and the tissues. After fulguration has been completed, a charred mass of tissue replaces the polyp. Fractional fulguration for indefinite periods may be necessary in order to destroy large lesions. In the case of pedunculated lesions, the site of attack may be the junction of the polyp and the pedicle. If this juncture cannot be exposed and sometimes even if it can, and the polyp or pedicle is large, the body of the polyp should be fulgurated. Care must be exercised when fulgurating a pedicle, because often the pedicle carries a large artery. Sometimes, also, the peritoneal surface of the bowel wall is drawn into the pedicle.

A proctoscope which is suitable for use while performing fulguration includes a built in suction tube through which smoke and gas can be exhausted from the bowel during fulguration (figure). If such suction is not available, gas within the bowel may ignite or explode. Also, a means must be provided for exhausting stool and fluids from the bowel. The surface of the lesion must be kept dry during fulguration.

In most instances, anesthesia is not necessary or desirable. General anesthesia never should be employed. When the lesion is close to the anus or actually involves it, or when adequate exposure cannot be obtained, caudosacral anesthesia may be employed.

Complications of the procedure are rare. Hemorrhage was encountered in only 7 instances in this series, and in only 1 was transfusion necessary. Hospitalization over night was deemed advisable in 5 cases. All complications occurred in cases in which there were massive lesions in the rectum and in which extensive treatment was required. In most of these, some degree of stricture of the rectum occurred. In 2 cases perirectal fistulas developed and in 1 a rectovaginal fistula.

CONCLUSIONS

1. Fulguration is an effective method, but great care must be used when selecting patients for this type of treatment.

2. Usually a pedunculated polyp may be fulgurated, regardless of its size or position in the bowel, provided that adequate exposure of the polyp and the entire pedicle can be obtained.

3. Large sessile polyps require more careful consideration. If such a polyp must be fulgurated, the ideal situation for it is on the posterior wall of that portion of the rectum which is not covered by mesentery. In that location there is little danger of injuring a vital structure, should it be considered necessary to destroy the wall of the bowel during the process of fulguration.

4. Malignant lesions deserve even more serious consideration than that which is given large sessile polyps. In order for treatment of these lesions to be at all successful, that portion of the wall of the bowel to which the growth is attached must always be destroyed. Consequently, such lesions should not be attacked by fulguration unless they involve the posterior wall of the rectum and only that portion of the rectum which lies distal to the peritoneal reflection. It is possible that malignant lesions which are not so ideally situated may respond favorably to fulguration, but they should not be so treated unless proper radical surgical measures are contraindicated or are rejected by the patient.

5. Large disseminated polypoid lesions, whether benign or malignant, and those which are associated with diffuse hyperplasia of the mucous membrane respond poorly to fulguration, either when it is used alone or in conjunction with radium therapy. Radical surgical treatment is indicated in such cases. In fact, the same attitude should be adopted in regard to such conditions as that which is maintained in connection with the management of malignant disease.

ABSTRACT OF DISCUSSION

Dr. Martin S. Kleckner, Allentown, Pa.: I have never heard a more concise or detailed presentation on this subject than that by Dr. Buie and Dr. Hill. I have not been surprised at the frequency with which early malignant conditions have been observed by the pathologist, because their observations closely approximate those of other investigators in this field. In using fulguration as a means of eradicating a simple adenoma or to blot out an existing adenomatous polyp which shows malignant changes, they deserve commendation, particularly when they have attempted fulguration to the polyps of the larger size when surgical intervention has been refused or senility and other infirmities make operation hazardous. The authors are justified in approaching this problem by attempting to remove these potential as well as early malignant growths by the method of electrofulguration. However, as one who has had a basic general surgical training, I would hesitate in attempting to remove those sessile early malignant polyps which measure 3 to 4 cm. and over in diameter by other than surgical intervention unless the contraindications were so outstanding that fulguration alone gave the patient the better chance for survival and cure. It is ofttimes very difficult to determine the resultant depth of the slough following fulguration, and I believe that only those trained in the use of this method and well acquainted with the anatom, of the terminal bowel should attempt polypoid removal because of possible perforation. I have had some very good results by the use of fulguration in the eradication of single polypoid growths. Its use in multiple polyposis is excellent in that the rectum may ofttimes be freed of all disease and facilitate future colonic surgical treatment. I wish to emphasize a few statements which in large measure coincide with the facts presented. 1. The smaller lesions invariably show a higher grade of malignancy when present than those of larger size. 2. Pedunculated growths are easier to eradicate but are not as frequently seen as the sessile lesions. 3. The palliative use of fulguration in cases in which operation is contraindicated, performed to maintain the lumen of the bowel and prevent obstruction, is frequently of great temporary value but dangerous. 4. Eradication of polyps from the terminal bowel by fulguration is an excellent procedure but is safe only in the hands of experienced operators. In multiple extensive polyposis, partial or complete colectomy may be necessary for cure, to be followed by ileosigmoidostomy or ileostomy alone. The proctologist (surgeon), the pathologist and the radiologist must combine their efforts in all these cases in order to determine the best operative method to use. 5. The use of radium in some cases and the roentgenologic aid in most cases usually is needed to provide satisfactory knowledge and cure.

Clinical Notes, Suggestions and New Instruments

SEVERE LITHIUM CHLORIDE POISONING WITH COMPLETE RECOVERY

Report of Case

ROBERT L. STERN, M.D.
Beverly Hills, Calif.

This syndrome followed the use of a commercial salt substitute containing lithium chloride, citric acid and potassium iodide. The changes which occurred were profound and severe, yet transient, and the patient made a rapid and complete recovery. The signal symptoms and signs as they successively occurred over a period of a week included anorexia, rapid change in personality, lethargy, dysphagia and pain on swallowing, bradycardia, cutaneous hyperesthesia and hyperalgesia, muscular hyperirritability, profound general and multiple myoclonus and mental obfuscation.

REPORT OF CASE

The patient was an 82 year old man previously rather vigorous and alert. He was hospitalized January 9 at the Cedars of Lebanon Hospital, Los Angeles, on arrival from another locale for further convalescence. Immediate previous diagnoses included: (1) simple fractures, right fourth, fifth and sixth ribs incurred Dec. 11, 1948; (2) rectal prolapse; (3) urinary bladder retention and infection; (4) bronchopneumonia with onset on Dec. 27, 1948, and (5) arteriosclerotic heart disease with slight cardiac hypertrophy and moderate congestive heart failure. He had a past history of various disorders of the urinary tract including stones, retention and infection and episodes of gouty arthritis in 1942 and 1947.

His convalescence was proceeding well, but he had exhibited some slight edema of the feet and an increase in congestion at the bases of the lungs. On January 12 his usual digitoxin dosage was increased from 0.1 to 0.2 mg. daily; he was given 1 cc. of meralluride sodium solution intramuscularly (and 2 cc. on the following day), put on a "salt-free" diet—which contained about 1 Gm. of sodium chloride daily—and given as salt substitute westsal® (a liquid containing lithium chloride, citric acid and potassium iodide). From January 12 to January 17, when westsal® was discontinued and a practically general diet offered the patient, but which he would not eat, about one-half bottle of the westsal®—or about 1¼ ounces—had been ingested. Although only minor diuresis occurred, the edema of the dorsum of the feet cleared and the congestion at the lung bases improved. On January 14 and January 15 he was given 0.2 mg. of digitoxin twice daily. By January 16 his weight had dropped 3 pounds (1.3 Kg.). Digitoxin was discontinued on January 16.

Results of laboratory investigations during his first week were as follows:

Blood sugar was 102 mg. and blood nonprotein nitrogen 39 mg. per hundred cubic centimeters. The urine had a specific gravity of 1.018, gave a neutral reaction and contained numerous pus cells. There were 4,600,000 red blood cells and 9,000 white blood cells, with normal differential count. Red blood cells and platelets appeared normal. Hemoglobin was 13.2 Gm. per hundred cubic centimeters. Blood sedimentation rate was 23 mm. in one hour, Wintrobe method. Urine culture revealed Pseudomonas aeruginosa. Phenolsulfonphthalein (intravenous) excretion test revealed a volume of 40 cc. with 17 per cent dye in the first at 15 minutes, 155 cc. with 14 per cent dye in the next at one hour. Total excretion in one hour was 31 per cent.

The patient continued to do well, attempting to be up a little too much walking about his room, except that he continued unable to void spontaneously. An indwelling catheter was used. Sulfadiazine and four days (3 Gm.) of dihydrostreptomycin therapy, and then mandelic acid therapy was given. On January 15, Dr. Kutzmann, the urologic consultant, ordered carbachol in an attempt to initiate urination. After the third tablet, the patient had a reaction consisting of profuse perspiration and the appearance of cardiac extrasystoles for the only time during my observation of him. Blood pressure was 148 systolic and 70 diastolic. The administration of atropine shortly stopped the reaction, and there was no residual evidence at the end of two hours, the heart rate and tone again being normal. Bladder retention was not helped. His abnormally reddened tongue was considered a deficiency sign, and crude liver extract and vitamin B complex were given intramuscularly daily.

On January 16 and 17 he appeared depressed and a little feeble and his appetite was not good. His weight was 140 pounds (63.5 Kg.). He had lost perhaps 2 pounds (0.9 Kg.) for the diuresis following the administration of meralluride was slight. On January 17 his heart rate continued regular, but varied from 60 per minute down to 48. An electrocardiogram on this date revealed no changes from the previous tracings and no evidence of digitalis intoxication. Digitoxin had been discontinued on January 16 when his appetite started to decrease.

On January 18 (ninth day after return to Los Angeles) he had distinctly failed. He was markedly depressed and physically feeble. His heart tones were of good quality, but the rate was now 42 to 40 per minute constantly. A fine punctate rash on his legs had spread somewhat, but chronic eczematous scaling patches on his neck and back which had been present for several years appeared as usual. He was not catheterized for thirty-six hours because he was so extremely concerned about not being able to void and he had a spillover of about 2 ounces at a time. At the end of this time he had a 1,000 cc. bladder retention although no distress, and an indwelling catheter was again replaced.

On January 19 he was further depressed and vomited his breakfast. All oral medication had been stopped three days previously. He vomited again only once or twice during the future course. His tongue was now beefy red, despite crude liver extract and vitamins intramuscularly for the five previous days. His heart rate was 50 and his blood pressure 130 systolic and 70 diastolic.

Blood cell count revealed 13.9 Gm. hemoglobin per hundred cubic centimeters, 4,950,000 red blood cells and 16,600 white blood cells with 81.5 per cent polymorphonuclear cells, 14 per cent lymphocytes, 2.5 per cent monocytes, 0.5 per cent myelocytes and 1 per cent metamyelocytes. The erythrocytes continued normal in size and shape; the neutrophils showed slight toxic granulation. Other laboratory tests revealed 55 mg. nonprotein nitrogen, plasma chlorides 545 mgm. per hundred cubic centimeters and carbon dioxide-combining power of 35 volumes per cent. He was given 500 cc. of sixth molar sodium lactate intravenously to combat the acidosis. On the evening of January 19 a few irregular fibrillary twitchings of the left arm were noted, but none were seen subsequently.

Dr. Maurice Rosenfeld and Dr. Verne Mason, internists, were in consultation on January 20. He had been reluctant to swallow for two days and now refused to, complaining of actual pain deep in the neck particularly on swallowing. His neck was not stiff and changes were not evident in the pharynx or the neck. He had for the first time distinct muscle guarding in the right side of the abdomen only and apparent tenderness in mid right hypochondrium. Palpation of any point in the right side of the abdomen caused distress and a distinct slow clonus of the right abdominal muscles only for a duration of about 5 to 10 seconds. He was given 2,000 cc. of 5 per cent dextrose in water and sodium chloride solution with vitamins in large doses (nicotinamide to total of 700 mg.).

Laboratory studies revealed blood creatinine 2.1 mg., uric acid 5.2 mg. and calcium 9.7 mg. per hundred cubic centimeters.

On January 21 (fifth day of retrograde change) he could be roused, at times answered rationally and responded to requests, but fell immediately back to sleep again. He continued to refuse to swallow. There was a great increase in physical muscle and skin irritability. Even stroking of skin caused flinching and thrashing about with evident distress. When a needle puncture of the skin was made for a blood test, he cried out. There was pronounced irregular clonus when his muscles were tapped. He mildly resisted flexion of the neck. He constantly held his legs crossed together in scissor fashion, and any attempt to uncross them caused strong adduction spasm with evident pain. Otherwise he was fairly quiet. His tendon reflexes remained unchanged, although perhaps slightly diminished. However, both of his great toes assumed a position of dorsiflexion. He continued afebrile. Palpation revealed a sensation of mass in the right midhypochondrium, and there was tenderness just under the rectus muscle.

A nasal tube was passed and he was given whole milk, added milk proteins, eggs, fruit juice, corn syrup, vitamin and brewer's yeast concentrated and nicotinamide to total about 2,000 cc. daily.

On January 22 he continued conscious but seemed asleep most of the time. He answered incoherently to questions. He continued to refuse to swallow. He had occasional jactitation and occasional marked spontaneous scattered clonus, not of any distinct muscle groups. The peculiar muscle and skin hyperesthesia continued but were not now constant on stimulation. His legs continued irritable in adductor spasm. The pulse rate rose to 70 once during the day, then went back to 48.

The urine had a specific gravity of 1.017, was acid, acetone negative, with numerous white blood cells and 0.36 Gm. urinary chlorides in twenty-four hours. Blood sodium was 313 mg., blood potassium 17 mg., calcium 9.4 mg. and phosphorus 2.8 mg. per hundred cubic centimeters. Serum albumin was 3.8 Gm. and serum globulin 3.0 Gm. per hundred cubic centimeters; the blood Kline reaction was negative. The electrocardiogram revealed no significant changes except that the T waves in lead 1 and in the chest leads appeared more normally upright than in previous leads, where T waves were low.

On January 24, lumbar spinal puncture was done and the fluid was clear under initial pressure of 120 mm. The laboratory reported total protein 16 mg. and sugar 81 mg. per hundred cubic centimeters; the Pandy test for excess globulin gave a negative reaction; the Wassermann reaction was negative and the gold curve was 0001100000. The urine was alkaline with normal acetone and bile, normal urobilinogen and 10 to 15 white blood cells.

On January 25 he answered rationally but did not speak voluntarily and had difficulty in articulating. He still kept his legs crossed and urgently resisted separation of them. As from the first, even the washing of his scrotum or the lower part of the abdomen caused much pain. The heart rate was now for the first time again at a steady 70, after eight days of bradycardia; the blood pressure was 130 systolic and 70 diastolic. The scaling erythematous patches on the anterior part of the neck and the back were clearing.

On January 26 he was rational but remembered nothing of the previous several days except that Dr. Nielsen had scratched his feet repeatedly. He was able to swallow satisfactorily, and intubation was discontinued. In the right side of the abdomen there was only slight resistance, no tenderness and the sensation of mass was almost gone.

Thereafter he improved rapidly. By January 31 the signs of muscle and skin irritability had cleared, although his soles were inordinately sensitive. Clonus cleared entirely on January 27. He had practically returned to his usual full mental alertness and was eating well and was up and walking about with no residuals.

By February 4 he was alert and cheerful. The indwelling catheter had been removed on February 1, and he continued to void spontaneously. He continued to have variable basal lung rales which were considered hypostatic. He walked and at no time exhibited any motor impairment. The old skin lesions on the neck and back cleared on high nicotinamide dosage, reappeared on dosages of 150 mg. daily and started to clear again on dosages of 400 mg. or more daily.

At the time of occurrence of this case, the possible toxic effects of lithium chloride were not known. The whole syndrome appeared with no evident reason in a convalescent patient who was doing well; who had, for four days before the onset been placed on a low sodium intake; who had some therapy to eliminate excess body fluid; who during this period had a most profuse induced episode of sweating, and who had during this four days ingested at will about 1¼ ounce liquid salt substitute (westsal®) consisting of lithium chloride, citric acid and potassium iodide. It is believed that an electrolyte disturbance occurred in the body fluids with either a toxic level of lithium occurring or a toxic effect from some change in the lithium chloride preparation. (One other patient reported practically simultaneously that a fresh, unopened bottle of westsal® had "turned blue.") Management consisted of early cessation of the medications, one day's therapy with intravenous administration of sixth molar sodium lactate and then dextrose and sodium chloride solution and thereafter five days of tube feedings of a full nutritional mixture. On this schedule the patient remained in a desperate state for five days, and then rapidly, recovered. Within a week, all evidence of the peculiar syndrome had cleared. It is believed that this case is one of severe poisoning due to westsal® with full recovery.

Council on Foods and Nutrition

This paper was prepared at the request of the Council and is one of a series appearing in the Journal. Later the entire series will appear in book form as the Council's Handbook of Nutrition.

FLUORINE AND OTHER TRACE ELEMENTS IN NUTRITION

F. J. McCLURE, Ph.D.
Bethesda, Md.

There have been important developments regarding the effects of fluorine on dental caries which justify the optimistic view that dental caries may be partially controlled by some form of fluoride therapy. The direct fluorination of drinking waters of large communal centers is in process of study as a caries control measure and represents a unique and heretofore unutilized approach toward a mass preventive in medicine and dentistry. The first direct fluorination of community water was begun on Jan. 28, 1945, in Grand Rapids, Mich. Other cities now artificially providing 1.0 part per million of fluorine in their drinking water are, Newburgh, N. Y.; Brantford, Ontario, Canada; Midland, Mich.; Sheboygan and Madison, Wis.; Evanston, Ill., Ottawa, Kan., and Marshall, Texas. No foodstuff in the average American diet can compare with drinking water containing 1.0 part per million or more of fluorine as a source of fluorine in human nutrition, but it cannot be said at this time that fluorine is an essential trace element even for purposes of dental health. Although it may become a recommended dietary procedure to supplement children's diets with an optimum quantity of fluoride, wherever a fluoride drinking water is not available, present evidence does not justify dietary addition of fluorine.

From the National Institute of Dental Research, National Institutes of Health.

Because of lack of space this article has been abbreviated in The Journal by omission of the bibliographic references. These will be included in the article as it will appear in the Council's Handbook of Nutrition.

Fluorine research has afforded a striking demonstration of the relatively narrow margin of physiologic benefit and physiologic toxicity which characterizes many trace elements. Optimum effects of fluorine on dental caries, thus, are associated with 1.0 part per million of fluorine in the drinking water,[1] whereas 1.5 parts per million or slightly more fluorine is the beginning level of endemic dental fluorosis.[2] The dietary conclusion is obvious, therefore, that the indiscriminate use of fluoride supplements must be condemned.

In addition to fluorine, manganese, cobalt, zinc and boron are discussed in this review, which continues in point of time from a previous review by Shils and McCollum,[3] published in an earlier issue of the Handbook of Nutrition. A number of other reviews concerning minerals in nutrition have appeared in recent years.[4]

FLUORINE

Fluorine and Dental Caries.—The epidemiologic evidence which demonstrated that excessive fluoride in drinking water is the cause of endemic mottled enamel [2] also suggested the fluorine–dental caries relationship, now conclusively associated with domestic waters of optimal fluoride content.[63] In one of the most important of the epidemiologic fluoride studies intensity of dental caries attack in school populations (12 to 14 year old children) in eight suburban Chicago communities was inversely correlated with 0.0 to 1.8 parts per million of fluorine in the drinking water.[64] Outside the United States similar confirmatory results have been reported.[65] Figure 1 is a summary graph of the results of the epidemiologic fluoride studies of Dean and his co-workers.[66]

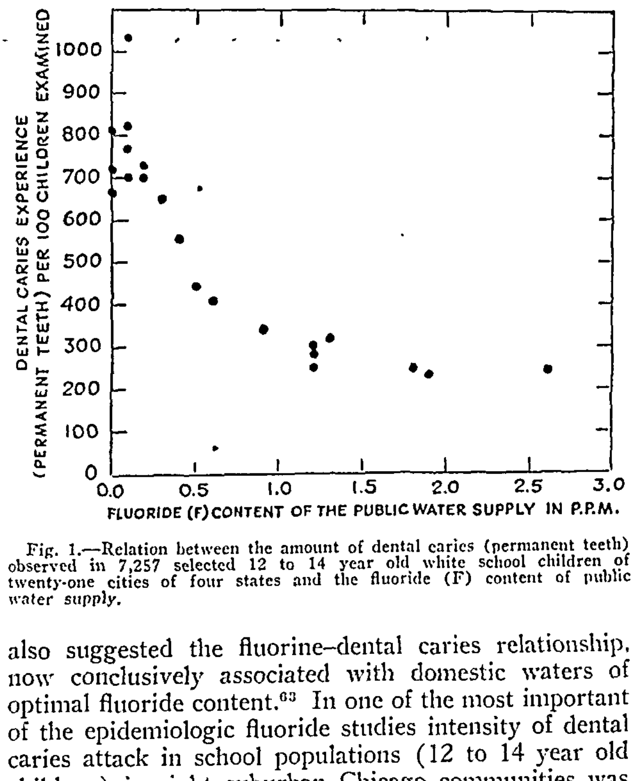

Fig. 1.—Relation between the amount of dental caries (permanent teeth) observed in 7,257 selected 12 to 14 year old white school children of twenty-one cities of four states and the fluoride (F) content of public water supply.

Whereas inhibition of caries has been demonstrated conclusively for 12 to 14 year old children continuously exposed to fluoride waters, only a few studies apply to older persons. Deatherage observed reduced caries in adult male inductees exposed to fluoride waters [67] starting even after their eighth birthday.[68] Weaver [69] extended his observations in England to older persons and studied effects of time of initial fluoride exposure on caries attack. He suggested that "fluorine is a caries-postponing rather than a caries-preventing factor," [70] a suggestion which does not discredit the significance of fluoride waters for caries control in younger persons. A recent report by McKay [70a] is contrary to Weaver,[70] and suggests that resistance to caries, as produced by exposure to fluoride drinking waters, continues into adult life. Both of these reports are based on small numbers of individuals. They permit no conclusions in these regards and mostly emphasize the uncertainties surrounding the mechanism and the duration of the fluoride anti-caries effects.

Experimental results give consistent support to the human caries–fluoride relation; i. e., (*a*) induced experimental caries in small animals is fluoride inhibited;[71] (*b*) dental tissues contain fluorine which may be classified as primary fluorine acquired during growth and calcification of the teeth,[72] secondary fluorine acquired after tooth eruption [73] and adsorbed secondary enamel fluorine,[74] acquired possibly by local oral enamel surface adsorption; (*c*) reduced solubility [75] and surface changes in enamel [76] and dentin [77] are attributed to fluoride reactions on dental tissues in vitro; (*d*) fluoride may affect oral bacterial activity [78] and exert antienzymatic effects possibly involved in causation of dental caries,[71b] and (*e*) the ameloblasts (enamel-forming cells) are extremely sensitive to fluorine.[79]

Perhaps the simplest explanation of the fluorine anti-caries action would point to fluorine in dental tissues. Limited analytic data reported by Armstrong and Brekhus [80] support the view that enamel of carious teeth contains less fluorine than enamel of sound teeth. The enamel but not the dentin showed this suggestive fluorine difference. A more comprehensive survey by McClure [81] refutes this idea as applied to individual teeth. Analyses of dentin and enamel of several hundred sound and carious teeth showing no signs of fluorosis and representing nearly 100 individuals did not reveal differences in fluorine content. The enamel of sound and carious teeth contained 0.0102 ± 0.0004 per cent and 0.0098 ± 0.0003 per cent fluorine respectively, and dentin from sound teeth contained 0.0241 ± 0.0010 per cent fluorine and from carious teeth 0.0225 ± 0.0007 per cent fluorine. Teeth of different types (incisors, molars, etc.) did not differ in fluorine content. It was suggested that an increase of fluorine in the entire dentition may account for an over-all reduction in dental caries experience, but that the individual carious teeth in a dentition cannot be expected to show consistently less fluorine in the enamel (or dentin) than do the sound teeth.

There are analytic data to show that mottled teeth do contain more then normal quantities of fluorine,[82] and fluorine in rats' incisor teeth also correlates closely with characteristic striations caused by fluorine in the diet.[83]

Variations in fluorine content per se, of dental tissues, in many respects would seem destined to affect their physical structure and biochemical properties in vivo in conformity with the in vitro experimental evidence cited. The remarkable caries-preventive results obtained by topical application of fluoride [84] suggest a change in enamel surface in vivo, due possibly to acquisition of additional enamel fluorine, via surface adsorption. Analytic procedure thus far has failed, however, to demonstrate any increased fluorine in topically treated teeth.[85]

When the causation of caries is discussed the question of enamel solubility usually arises, and numerous investigators look to fluorine to so alter enamel and dentin solubility that acid decalcification by bacterial activity will be remarkably retarded. Here again the explanation may be overly simplified when the question is raised as to what quantity of fluorine in the teeth may be innocuous, and at the same time have a significant solubility-reducing effect.

Because fluorine is a powerful antienzymatic agent [86] it is suggested that fluorine in the teeth acts antienzymatically. There is little or no evidence in vivo to support this idea. The effect of fluorine on salivary amylase seems inconsequential,[87] and fluorine in saliva is not correlated with ingestion of fluorine.[88]

Dental Caries and Fluoride Medication.—In the present state of our knowledge the primary objective in fluoride preventive dentistry is to incorporate optimum quantities of fluorine into dental tissues by the most effective, efficient and lasting means which can be devised. Thus, experimental fluorination of communal drinking water is an attempt to duplicate mass population exposure to natural fluoride waters and thereby incorporate, possibly, an optimal quantity of fluorine in developing teeth. Results from these experiments will not be forthcoming for several years, although bacteriologic results of somewhat uncertain value have already been published.[89]

The beneficial as well as negative results attending the topical application of solutions of sodium fluoride and other fluorides are summarized in the table. While use of fluoride topically seems extremely promising, variations in the procedure, in the solutions used, etc., need to be studied.[84h]

McClure [91] estimated the milligram quantities of fluorine ingested via drinking waters containing 1.00 part per million of fluorine and suggested that the direct addition of about 1.0 mg. of fluorine as sodium fluoride daily to children's diets during the first eight years of life be considered as a caries-preventive measure. A dietary supplement of fluoride seems to have possibilities in caries control, but care should be exercised in the use of fluoride tablets. Their use is contraindicated where the drinking water contains 0.5 to 1.0 part per million or more of fluorine.

A great number of fluoride-containing tablets, for daily consumption in lieu of a fluoride drinking water, have appeared on the market. The value of these tablets has had no satisfactory demonstration, although several attempts in this direction have been made.[90] Most of these tablets contain calcium fluoride, or bone meal, and some provide vitamins, whereas there is no evidence that calcium, phosphorus or any of the vitamins enhance the fluorine caries-preventive effect.

The idea is erroneous that edible foods grown in areas where fluorine in the local water is above normal are high in fluorine content. Analytic data and fluoride fertilization studies,[92] and the fact that the majority of fluoride-bearing waters are not surface waters but come from deep wells,[93b] all contradict this erroneous idea. The tea leaf and certain sea foods [83] are exceptionally high in fluorine, but in general no raw foods can be implicated in the causation of fluorosis or in the "fluoride prevention" of dental caries.[93] Small increments of fluorine may be added to certain foods when they are cooked in fluoride waters.[94]

Any increase of fluorine in cows' milk due to extra fluorine in the cows' ration or drinking water is not to be expected, contrary to some such suggestions.[95] All the evidence reveals no elevation of fluorine in cows' milk due to additional fluorine in the ration or drinking water.[96] It should be emphasized, certain industrial exposures being disregarded, that water-borne fluorine is the major fluorine exposure associated with human population groups.

Effects of Fluoride Domestic Waters.—When it became evident that 0.5 to 1.0 part per million of fluorine in drinking water did not cause mottled enamel,[93a] direct fluorination of public water supplies as a caries-preventive measure was contemplated, although certain health hazards which might arise from this public practice were not to be ignored.

Clinical, epidemiologic and experimental evidence [96c] suggested a hazard of accumulative toxic fluorosis, particularly if a high percentage of the water-borne fluorine was retained in the body. Particularly incriminating are the reports from fluoride areas outside the United States which suggest toxic effects of excessive quantities of fluoride in drinking waters, combined with fluoride-contaminated food. A discussion of these reports has been presented elsewhere.[96c] In brief, the consensus is that the fluoride exposure of the afflicted (fluorosed) native people exceeds any level of fluoride encountered in the United States, or that other local factors and lack of adequate control data throw doubt on the results reported.[97]

Effects of Topical Applications of Fluorides

Number of Subjects	Age Range	Treatment: Solution	Treatment: Applications	Length of Study	Reduction in Caries Incidence, Percentage	Ref. No.
90	10-13	0.1% NaF	3	1st yr.	46	84b

* Acidified to p_H 4.5.

In an attempt to assess the hazard of cumulative fluorosis from fluoride waters, an extensive survey of the fluorine concentration of urine specimens of high school boys and of young selectees of the armed forces of the United States was made by McClure and Kinser.[98] The data indicate that upward of 90 per cent of water-borne fluorine (in concentrations of 0.5 to 4.5 parts per million of fluorine) is eliminated in the daily urine of teen age boys and young men. The results of this fluorine excretion study are shown in figure 2.

Fluorine balance studies [99] furnish additional evidence that the adult human body eliminates the major portion of food-and-water-borne fluorine when the quantities ingested do not exceed 4.0 to 5.0 mg. of fluorine daily. According to these experiments,[100] body sweat may contain appreciable quantities of fluorine which may be related to the fluorine being ingested.[88b] McClure also found negative effects of water containing 0.5 to 4.5 parts per million of fluorine on age-height-weight-relations and bone fracture histories of high school boys and young inductees.[101] Although further studies of population groups exposed to fluoride waters are undoubtedly desirable, it seems unlikely that prolonged ingestion of fluorine via a domestic drinking water containing 1.0 to 1.5 parts per million of fluorine, or perhaps more, presents a public health hazard.

Fluorine Physiologic Effects and Requirement.—According to Lawrenz [102] the growing rat requires less than 27 micrograms of fluorine per kilogram, which agrees with previous evidence [103] that fluorine probably has no essential function in the rat. Our present knowledge also does not permit classification of fluorine as an essential element in human nutrition even as regards dental health. The presence of fluorine in dental tissues or in other body tissues is not evidence that fluorine is essential.

The metabolism of fluorine by the rat was the subject of extensive study by Lawrenz and Mitchell, and Lawrenz, Mitchell and Ruth. Their conclusions are based largely on balance studies and are summarized elsewhere.[102]

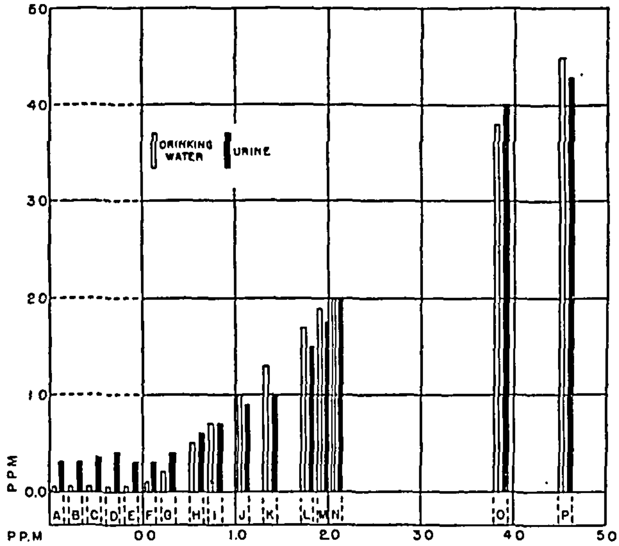

Fig. 2.—Relation of fluorine in drinking water to fluorine content of urine: *A*, New Hampshire; *B*, Chicago; *C*, Washington, D. C.; *D*, Waukegan, Ill.; *E*, Little Rock, Ark.; *F*, Quincy, Ill.; *G*, Indianapolis; *H*, Oklahoma City; *I*, Elgin, Ill.; *J*, Aurora, Ill.; *K*, Joliet, Ill.; *L*, Monmouth, Ill.; *M*, Galesburg, Ill.; *N*, Lubbock Glider Field; *O*, Lubbock, Texas, and *P*, Amarillo, Texas.

It is generally difficult to apply animal experimental fluoride results to fluorine exposure via domestic fluoride waters, because of the disproportionate quantities of fluorine involved, variations in species susceptibility and duration of exposure. Fluorine ingestion from domestic waters, even in areas of greatest water fluorine concentration,[62] would rarely exceed 8 to 10 mg. daily (i. e., less than 0.10 mg. per kilogram in the average adult), whereas animal experimental diets usually provide 5.0 mg. or more fluorine per kilogram.[104] In a recent study, growth, serum calcium and phosphorus, hemoglobin and blood coagulation time were not altered by feeding 5 mg. fluorine per kilogram, in some instances as long as one year, to 21 litters of dogs, involving 99 dogs.[104c] A reduction in blood hemoglobin in rats receiving 50 parts per million of fluorine as sodium fluoride in their drinking water was reported by Ginn and Volker [105] but was not confirmed in a subsequent study by McClure and Kornberg.[106]

The effects of fluorine on enzymic processes were recently reviewed thoroughly by Borei in connection with the report of his extensive studies on the inhibition by fluoride of oxidative processes in the cell.[86]

MANGANESE

Effects of Manganese Deficiency.—There is consistent evidence regarding manganese deficiency to the effect that (*a*) rats and mice react similarly, (*b*) there is a congenital debility in the young, (*c*) manganese is essential for growth in rats and mice, (*d*) there is testicular atrophy and sterility, (*e*) there is decrease in arginase activity, in vitro, (*f*) poor bone formation and bone changes in manganese-deficient rats and chicks are similar, (*g*) chicks and rats seem to show a similar need for manganese for normal functioning of the nervous system and (*h*) there are lowered hemoglobin concentration and interference with blood regeneration.[5] Lameness in pigs and more especially perosis in chicks are well established effects of manganese deficiency.[5b]

Disagreement was evident among the observations regarding the reproductive ability of female rats and the viability of their young,[5a] and Shils and McCollum [5a] suggested the possibility of three distinct stages of manganese deficiency in the female; i. e., (*a*) viable but defective young are born, (*b*) young are born but die shortly, and (*c*) a disturbed estrus cycle produces sterility.

Wachtel, Elvehjem and Hart [5c] in a paired controlled feeding experiment, as well as via ad libitum feeding, in rats produced additional evidence of (*a*) impaired growth, (*b*) less ash in bone, (*c*) a slight progressive anemia and (*d*) decreased hemoglobin regeneration. They found also a two to three fold increase in blood serum phosphatase activity and no significant change in bone phosphatases. Amdur, Norris and Heuser,[6] from a more recent, also controlled feeding experiment, reported a small but significant reduction in the alkaline phosphatase in bones of manganese-deficient rats. Both chicks [7] and rabbits [8] on manganese-deficient diets have shown reduced phosphatase activity. In this later rabbit study [8] food intake of control and deficient animals was equalized according to Mitchell's paired feeding technic and a detrimental effect of manganese deficiency on growth and on fresh weight, percentage of ash, total ash, density and length of humerus, was demonstrated.

After characteristic symptoms of manganese deficiency in the rabbit had been established, it became possible to determine to some extent the nutrient requirement of the element. Thus, Smith and Ellis and others [9] found that rabbits receiving but 0.3 mg. of manganese daily had normal bone, normal phosphatase activity of bone and normal arginase activity of the liver, but there was the suggestion that this much manganese was not sufficient for normal growth.

Physiologic Effects of Manganese.—Experiments related to several physiologic effects of manganese have appeared recently. The suggestion by Rudra,[10] that manganese played a role in the synthesis of ascorbic acid, was not confirmed.[11] Skinner and McHargue [12] presented evidence in support of a role of manganese in the synthesis of hemoglobin by showing, with rats, that manganese combined with iron and copper gave better results than iron and copper alone. Skinner and McHargue [12] suggested that manganese may supplement the action of copper. This is one of several conflicting reports on the relations of manganese and copper in hemoglobin synthesis.[13]

Manganese chloride administered subcutaneously in a single dose to white rats, in dosages greater than 180 mg. per kilogram, caused an enamel hypoplasia.[13b] An interesting observation reported by Amdur, Norris and Heuser [14] is that manganese tended to prevent the deposition of fat in the liver of rats. An interaction between choline and manganese was indicated by the fact that this lipotropic action of manganese was much greater when the choline content of the diet was lowest. Bone fat as well as liver fat was reduced by both manganese and choline.

The addition of 10 Gm. of manganese to the daily ration of dairy cows changed the manganese content of cows' milk from 21.9 to 64.5 parts per million.[15] This appears to be the only such report of an induced change in the manganese content of milk.

Radiomanganese Studies.—Several studies utilizing *radiomanganese have appeared. Two studies with* chicks [16] and rats [17] confirm evidence of practically complete elimination of manganese through the feces. In both manganese-deficient and control chicks [16] the major part of orally administered manganese was excreted. Labeled manganese given orally did not appear in bone, indicating that the manganese requirement of bone may be small.[16] Orally ingested manganese is poorly absorbed, even in the fasting animal.[17]

As has proved true in regard to many studies on unlabeled manganese in numerous animal species,[18] radiomanganese studies show the liver to be a most active organ in manganese metabolism.[19] From 50 to 75 per cent of the intestinal excretion of labeled manganese was estimated to come from the bile.[17] In the chick the role of manganese in hepatic function cannot be identified with arginase,[20] since chick liver does not contain arginase.

In experiments on the distribution of intravenously administered colloidal sols of manganese dioxide, containing about 1 per cent of 310 day manganese, to human beings and dogs, liver manganese in human beings also appeared to be high.[21] In the opinion of these workers [21] the pancreas as well as the liver may have special significance in manganese metabolism.

Manganese and Enzyme Action.— Manganese, although increased twentyfold in the diet of rats, had no effect on the activation of cocarboxylase in vivo, as measuured by the concentration of bisulfite-binding substances in the blood.[22]

Smith [23] studied the mechanism of manganese activation of l-leucine-aminoexopeptidase and expressed the belief that the action of this metal ion is due to the formation of a true metal-protein-enzyme compound.

The micro determination of manganese has been studied from three different angles, (*a*) microcolorimetric,[24] (*b*) microbiologic [25] and (*c*) a method utilizing the catalytic properties of manganese in an oxidation reaction.[26]

COBALT [26a]

Cobalt is required by ruminants but, strangely enough, not by other grazing animals (horses) or other species.[27] Attempts to demonstrate a cobalt deficiency in rabbits with a diet containing 0.0024 part per million of cobalt failed [28] and no deficiency symptoms result in rats,[29] or else the requirement is extremely small; i. e., less than 0.003 part per million daily.[29c] It has become increasingly evident that cobalt may not act directly on the ruminant host but within the rumen [30] where micro-organisms, concerned possibly with the synthesis of some of the B vitamins, may be affected.[28] In keeping with this idea Ray, Weir, Pope and Phillips [31] have obtained data which indicate a slightly lower concentration of nicotinic acid and possibly of the vitamin B_6 group in the blood of cobalt-deficient sheep.

Cobalt Metabolism Using Radioactive Cobalt.—When labeled cobalt in trace physiologic quantities is used, results are consistent in indicating, via measurements of body retention and tissue concentration, that the direct requirement of cobalt by ruminants must be small indeed, and, if required by other animals, the quantity is also small.[32]

Orally administered radiocobalt was only poorly absorbed by rats,[29] and a large portion appeared in the feces. Excretion of absorbed cobalt was chiefly by way of the urine. The bile is an important excretory path, and considerable cobalt was found in the liver, which suggested a role of cobalt in liver metabolism.

No significant amounts of injected cobalt reached rumen contents, and little rumen-ingested cobalt (via a rumen fistula) reached the blood.[32b] Orally administered labeled cobalt was 80 per cent eliminated in the feces, 0.5 per cent in urine.[32c] Relatively insignificant absorption was indicated by failure to find cobalt in blood, milk or saliva. Labeled cobalt injected intravenously in dogs did not appear in significant amounts in the pancreatic juice, but a total of 2.0 to 5.0 per cent was eliminated in forty-eight and seventy-two hours respectively in the bile.[32d]

Cobaltous acetate (500 mg. daily) in rations of dairy cows increased the cobalt in milk from 0.6 mg. up to 2.4 mg.[32e] Comar and Davis [33] compared the distribution of injected radioactive cobalt in swine, rabbits and young calves and found no evidence of species differences. Their findings "support the view that the major function of cobalt in the ruminant is a localized action in the rumen, but do not exclude the possibility of a hematopoietic function."

The foregoing evidence, which implicates the liver as an important depository for radiocobalt, is in agreement with the analytic data of Askew and Watson,[34] which showed that radioinactive cobalt given to deficient sheep accumulated in greatest amount in the liver, with only slight increases in spleen and kidney.

Cobalt Polycythemia.—An exhaustive review of dietary factors (vitamins, amino acids and minerals) which are concerned in erythropoiesis has appeared recently.[35] Among the minerals involved—iron, copper and cobalt—cobalt is unique; i. e., a deficiency of cobalt results in anemia, small amounts of cobalt produce erythropoiesis and larger amounts depress erythropoiesis. Although symptoms of endemic cobalt diseases are not specific, involvement of the erythropoiesis is indicated by the anemia which is generally observed in cobalt-deficient animals.

Cobalt polycythemia is easily produced in a number of animal species,[34] but the mechanism is still unknown. A number of reports on this subject have appeared recently.[36] Wintrobe [36g] studied the effect of cobalt on the anemia produced by inflammation induced by injection of turpentine and found it was largely overcome in the rat by cobalt. Cobalt polycythemia was developed in rats regardless of the addition of choline or methionine to the diet, but the addition of cystine was distinctly inhibitory.[36f]

[26a] Since completion of this review E. L. Rickes, N. C. Brink, F. R. Koniuszy, T. R. Wood and I. T. Folkers, (Science **108:** 134, 1948) have reported the presence of cobalt in the new B_{12} vitamin. Inasmuch as this vitamin is identified with remarkable effects in pernicious and other anemias, this discovery may explain some of the relations of cobalt to blood chemistry and may likewise extend the requirement of cobalt to other animals as well as ruminants.

A role of cobalt in cell metabolism is suggested by its activating effect on arginase.[37] Cobalt is also an effective inhibitor of growth and respiration of various micro-organisms, animal tissues and tumors. The action of histidine in overcoming this cobalt inhibitory effect is being studied.[38]

ZINC

A comprehensive review of zinc, emphasizing its toxicity, has been presented.[39] Prior to this survey[39] it was surmised that use of zinc in war production might have produced unsuspected features of zinc toxicity. No new toxic manifestations were noted, however, and the usual precautions in industrial production and use of zinc are still necessary.

Interest in a requirement of zinc is stimulated by evidence of the presence of zinc in purified carbonic anhydrase.[40] Use of radiozinc (Zn^{65}) has furnished new information on zinc metabolism.[41]

A need for zinc by the rat has been known for some time,[42] but it has been more difficult to determine in the mouse.[43] However; zinc starvation in mice did produce retarded growth, localized alopecia and affected hepatic and renal catalase.[44] A change in hepatic esterase, or concentration of riboflavin in liver and kidneys, changes in enamel and dentin and distinctive gross symptoms did not occur in this experiment.[44] Food consumption was ad libitum, however, and it would be of interest to confirm deficiency effects[44] under conditions of controlled feeding.

While a number of experiments suggest that the pancreas is involved in zinc metabolism,[45] evidence is contradictory regarding the relations of zinc and insulin.[46] In support of the view that the acinar portion of the pancreas may be associated with zinc metabolism, Montgomery, Sheline and Chaikoff[41a] found 11 per cent of administered radiozinc (Zn^{65}) excreted in the pancreatic juice of the dog in fourteen days. Maximum excretion in bile was only 0.4 per cent in eight days. Radiozinc was found in large amounts in juice obtained from an isolated loop of the duodenum. Sheline, Chaikoff, Jones and Montgomery[41b] injected minute quantities of zinc intravenously in dogs and mice and found that by far the largest fraction was eliminated in the feces. In dogs and mice the most active turnover of radiozinc was in liver, pancreas and pituitary gland. The least activity occurred in red blood cells, brain, skeletal muscles and skin.[41c] The extensive distribution of zinc in the animal body and its presence in important intestinal secretions gain support from these results.[41b,c]

Forty-two zinc balances on normal human patients reported by McCance and Widdowson[47] presented a condition also noted for injected radiozinc[41b,c]; i. e., practically all food-ingested zinc was eliminated in the feces. Normally 0.3 mg. zinc daily was excreted in the urine, and this quantity did not vary with the intake of zinc by mouth or by injection. Patients with albuminuria excreted about seven times the normal amount in urine, although this amount of zinc was not correlated with the degree of albuminuria. In contrast with this result,[47] Fairhall and Hoyt[48] previously found no relation of zinc to urinary albumin, but zinc was somewhat increased in the urine of uremia and tuberculosis. It would appear that the kidney normally has little or no zinc excretory function and does not vary its excretion in relation to dietary zinc or even when plasma zinc is increased after zinc injection. Traces of zinc in the urine as suggested by McCance and Widdowson[47] possibly represent an end product of some metabolic function of the kidney itself.

Zinc toxicity studies in rats provided Smith and Larson[49] with evidence of an antagonistic effect of copper and liver on reduced growth and hemoglobin levels associated with zinc toxicosis and called further attention to the inter-relation and interdependence of mineral elements in physiologic effects.

Although important relations to numerous enzyme systems[50] and certain animal experiments[51] suggest a human need for zinc, there is no direct information on this requirement. In a report by Stevenson[52] the possibility of a human zinc requirement was remotely suggested by evidence of low carbonic anhydrase activity in the blood of premature infants. Wide distribution in plants and animals, however, contraindicates a deficiency of zinc occurring in practical animal and human nutrition.

BORON

Boron occurs extensively in animal tissues,[53] but no evidence of a boron requirement in animal nutrition has been noted. Both oral ingestion of boron and absorption from boric acid, applied in the form of an ointment or a saturated solution, may cause serious and even fatal cumulative boron poisoning.[54]

Teresi, Hove, Elvehjem and Hart[55] prepared a ration lower in boron than that previously used.[56] Although the animals failed to eat the ration properly, it was indicated that a boron intake of 0.6 microgram per rat per day would probably satisfy normal growth.

In plant nutrition boron is poorly absorbed from mediums of low potassium content.[57] Assuming that a similar relation might exist in animal nutrition, Skinner and McHargue[58] studied the response of rats to boric acid and borax supplements in rations low in potassium. Due to extreme potassium deficiency all the animals grew little, but boron supplements accounted for longer survival periods, and after twenty-one days the rats on boron supplements contained 47 per cent more glycogen in their livers than the controls not given boron supplements. Stores of body fat were favored by "liberal supplementation" with boron compounds. The variable food consumption by rats on the two rations was not considered.

In a similar study, Follis[59] did not find heart and renal lesions in the rat due to potassium deficiency any different with and without boron supplements and, contrary to the results of Skinner and McHargue,[58] boron had no effect on growth or survival time.

An eleven to sixteen day boric acid regimen (3 Gm. daily) was studied in 4 normal adults.[60] This much boron was not particularly toxic to these adults, as indicated by no effects on basal metabolism or other effects being noted.

Excretion of borate by the dairy cow was studied in forty day balances in 2 Ayrshire cows.[61] Feeding 16 to 20 Gm. borax daily caused the milk concentration of boron to rise from 0.7 to 3.0 parts per million, which was not considered a public health hazard.[61] No diuretic effects, loss in weight or other ill effects occurred. A retention of boron in the body was not detectable, and boron excretion rapidly returned to normal at the end of experimental feeding.

Council on Physical Medicine

The Council on Physical Medicine has authorized publication of the following article. Howard A. Carter, *Secretary.*

ABSTRACT OF THE MINUTES OF THE MEETING OF THE COUNCIL ON PHYSICAL MEDICINE, DECEMBER 10 AND 11, 1948

The annual meeting of the Council on Physical Medicine was held Friday and Saturday, December 10 and 11, 1948, at the Headquarters of the American Medical Association. Those members present were: Drs. Morris A. Bowie, John S. Coulter, Anthony C. Cipollaro, William E. Grove, W. E. Garrey, Andrew C. Ivy, Frank H. Krusen, Frank R. Ober, George M. Piersol and Derrick Vail.

Dr. John S. Coulter was reelected chairman and Dr. Frank H. Krusen vice-chairman. Dr. Krusen served as acting chairman of the meeting.

Dr. W. E. Garrey presented a report of the Committee on Scientific Research of the Council, and the discussion which ensued pointed out the necessity of investigating the fundamental problems in the therapeutic use of radiation and atomic energy.

Dr. Howard A. Rusk of New York addressed the Council on the problems of residencies in rehabilitation. After much discussion it was apparent that the aims and purposes of physical medicine and of rehabilitation were very much alike and the Council voted to ask the Board of Trustees to consider favorably a change of the name of the Council on Physical Medicine to Council on Physical Medicine and Rehabilitation.

Considerable discussion was given to an article published by the Council entitled "Rebates," which dealt with the marketing of spectacles and hearing aids and with the ethical problems involved. The Council voted to withdraw the article and moved that a committee of three consisting of Dr. Ober, chairman, and Drs. Grove and Vail represent the Council at a meeting with the Judicial Council to discuss the problems relative to marketing hearing aids and spectacles by members of the medical profession.

The Committee on Field, Scope and Present Status reviewed the list of products considered by the Council. To this list of apparatus were added electrically heated bed coverings and trusses. The Council voted not to consider mattresses and auditory training units.

Progress reports on the activities of the various consultant groups were presented by the following: Dr. William E. Grove, Consultants on Audiometers and Hearing Aids; Dr. Derrick Vail, Consultants on Ophthalmic Devices; Dr. George Morris Piersol, Consultants on Clinical Thermometry, and Dr. Andrew C. Ivy, Consultants on Contraceptive Devices.

The Council voted that the Consultants on Roentgen Rays and Radium and Consultants on the Medical Aspects of Atomic Energy be henceforth combined and known as the Consultants on Roentgen Rays, Radium and Medical Aspects of Atomic Energy.

Reports were given by the members of the staff on artificial limbs, roentgen rays, radium and medical aspects of atomic energy, education, electrocardiographs, electroencephalographs, occupational therapy and respirators.

Reports were read on the present status of the Committee on American Health Resorts and the Committee on Radiation.

The Council voted to revise the "Glossary on Atomic Energy" and publish it.

Some discussion was devoted to the status of vaporizers for the distribution of glycol vapor recommended by the manufacturers for protection against cross infection. Although the scientific evidence available shows that germs may be destroyed in a confined space under laboratory controlled conditions, it was the opinion of the Council that the evidence did not justify the acceptance of generators of glycol vapors in practical applications, such as schools, offices, theaters and public buildings, because the results are not convincing.

Dr. Edith Quimby was appointed as a member of the Consultants on Roentgen Rays, Radium and Medical Aspects of Atomic Energy. Dr. H. Worley Kendell was appointed to fill the place vacated by the death of Dr. Frank Ewerhardt as a Consultant on Education. Dr. Howard Burchell was appointed to fill the place vacated by Dr. Barnes as a Consultant on Electrocardiographs.

Dr. Cipollaro moved that a member of the Council be appointed an ex officio member of each group of Consultants. The Chairman then appointed the following with the approval of the Council:

Consultants on Artificial Limbs—Dr. Ober, ex officio.
Consultants on Roentgen Rays, Radium and Medical Aspects of Atomic Energy—Dr. Cipollaro, ex officio.
Consultants on Audiometers and Hearing Aids—Dr. Grove, ex officio.
Consultants on Clinical Thermometry—Dr. Piersol, ex officio.
Consultants on Contraceptive Devices—Dr. Ivy, ex officio.
Consultants on Education—Dr. Coulter, ex officio.
Consultants on Electrocardiographs—Dr. Garrey, ex officio.
Consultants on Electroencephalography—Dr. Piersol, ex officio.
Consultants on Occupational Therapy—Dr. Bowie, ex officio.
Consultants on Ophthalmic Devices—Dr. Vail, ex officio.
Consultants on Respirators—Dr. Williams, ex officio.
Committee on American Health Resorts—Dr. Krusen, ex officio.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

Austin Smith, M.D., *Secretary.*

RABIES VACCINE (ULTRAVIOLET IRRADIATION KILLED).—Brains of rabbits paralyzed by infection with fixed rabies virus are harvested, emulsified and brought to a desired concentration by suspension in isotonic solution of sodium chloride; the suspension is filtered and a continuously flowing thin film is irradiated with ultraviolet light and dispensed in vials containing sufficient material for a daily dose.

Actions and Uses.—Rabies Vaccine (Ultraviolet Irradiation Killed) is employed for the prophylaxis of rabies.

Dosage.—Contents of one vial subcutaneously daily for 14 to 21 days. For severe exposure-bites on face or adjacent to central nervous system, 21 doses, two daily for the first three to seven days, then one dose daily.

Pitman-Moore Company, Indianapolis

Rabies Vaccine (Ultraviolet Irradiation Killed Virus): 1 cc. vials packaged in units of seven vials of a 10 per cent suspension. Preserved with sodium ethylmercurithiosalicylate 1 : 10,000.

E. R. Squibb & Sons, New York

Rabies Vaccine (Ultraviolet Irradiation Killed Virus): 2 cc. vials packaged in units of seven vials of a 5 per cent suspension. Preserved with sodium ethylmercurithiosalicylate 1 : 10,000.

PENICILLIN (See New and Nonofficial Remedies 1947, p. 144).

The following dosage forms have been accepted:

Bio-Ramo Drug Co., Baltimore 1, Md.

Crystalline Penicillin G Sodium: 200,000, 500,000 unit vials and 1,000,000 unit vials buffered with sodium citrate.

Premo Pharmaceutical Laboratories, Inc., New York

Crystalline Procaine Penicillin G in Oil: 300,000 units per cc., in sesame oil, 1 cc. disposable syringes and 10 cc. vials. Suspended with aluminum monostearate 2 per cent W/V.

Schenley Laboratories, Inc., New York

Crystalline Penicillin G Potassium: 100,000, 200,000, 500,000 units, 20 cc. vials; 1,000,000 units, 50 cc. vials.

TRANSFUSIONS OF BLOOD FROM PREGNANT WOMEN FOR RHEUMATOID ARTHRITIS

The beneficial effect of thirty of thirty-four pregnancies in 20 patients with rheumatoid arthritis was reported in 1938 by Hench.[1] A "marked" to "complete" remission of the arthritis resulted. Seventeen of the 20 patients experienced notable relief of their rheumatoid arthritis each time they became pregnant. Articular relief began during the first trimester in about 90 per cent and in the second trimester in about 10 per cent of the patients who experienced amelioration. Relief was complete in about 60 per cent of effective pregnancies, almost complete in about 15 per cent and notable in the remaining 5 per cent. After parturition, the phenomenon of articular relief ended in about 50 to 55 per cent of the cases within one to seven weeks, and in between eight and twelve weeks in 10 per cent. Relief rarely lasted from four to twenty-four months. The factors of lactation, length of time in bed and approach of postpartum menses did not govern the duration of postpartum relief. Rheumatoid arthritis rarely begins during pregnancy. Hench concluded that pregnancy initiates a physiologic state which is decidedly beneficial (at least temporarily) to patients with rheumatoid arthritis (as well as to those who have certain other rheumatic disorders).

Barsi[2] reported the use of transfusions of blood from pregnant women in 6 cases of rheumatoid arthritis and noted that a "cure" occurred in 4 and that improvement occurred in 2 of the cases. The period of follow-up was from two to six months. More recently[3] he has briefly reported 28 cases of rheumatoid arthritis ("seemingly hopeless") in which transfusions of 300 cc. of blood from pregnant women were given "several times." "Sixty-four per cent recovered or improved," while in 6 cases a complete remission was said to have resulted and 4 were "cured" for the three to five years of follow-up study. Benefit was thought to be "independent of whether or not the transfusion caused a febrile reaction."

The claims of Barsi (Basch) have not been confirmed by the reports of five other groups of investigators.[4] These investigators describe the use of transfusions of blood from pregnant women given to 85 rheumatoid patients. Improvement was not noted in 56 per cent, slight to moderate improvement was observed in 28 per cent, and decided improvement occurred in 16 per cent. In no instance was a "cure" reported.

Results of a similar degree have been reported following the use of transfusions of blood from nonpregnant persons.[5] More recently (1947) the results of transfusions (two to thirteen, average five) of 300 cc. of normal blood every seven to ten days in 24 cases of rheumatoid arthritis (mostly severe) were reported by Appelqvist and Holsti.[6] This procedure was said to have produced "favorable but rarely dramatic" improvement. A "definite remission" occurred in only 1 patient, who also received gold therapy. These authors believe that the temporary improvement paralleled febrile reactions to the transfusions.

With the exception of the (unconfirmed) reports of Barsi (Basch), results of transfusions of blood from pregnant women given to patients with rheumatoid arthritis are not notably superior to those following the use of transfusions of blood from nonpregnant persons.

Repeated observations of many physicians have confirmed the potentially favorable effect of pregnancy on the course of rheumatoid arthritis. The phenomenon is a noteworthy one even though the mechanism by which it is accomplished is, as yet, unrecognized. The pregnant patient with rheumatoid arthritis circulates in excess of ten times the amount of blood used in transfusions obtained from pregnant women and only is able to sustain the resulting remission in the rheumatoid arthritis for an average of about one to seven weeks post partum. The expectation that significant, prompt and sometimes permanent alteration of the course of rheumatoid arthritis would result from transfusion of 300 cc. of blood from a pregnant woman (even when repeated) would seem remote. That such spectacular or even notably beneficial effects do result specifically from such a procedure remains to be established.

DEATHS IN CHILDREN FROM RHEUMATIC FEVER AND HEART DISEASE

A recent national statistical study of rheumatic fever and heart disease in children by Wolff[1] reveals that 14,575 deaths from all forms of heart disease occurred among those under 20 years of age in the years 1939 to 1941. A minimum of 12,000 deaths was considered to be caused by acute rheumatic fever and its aftereffects. Compared with six other leading causes of death, with increasing age rheumatic fever held an increasingly high place among the fatal diseases of the white population. In the nonwhite population, the greatest killer was tuberculosis, especially for girls entering the childbearing age. In spite of these facts, a comparison with mortality rates for two previous decades and the single years 1942, 1943 and 1944 demonstrated that rates for heart disease in these age groups for white children was showing a distinct decrease. The decrease was less definite in the nonwhite group. Nonwhite children showed a generally higher mortality for rheumatic fever than white children. Although the difference in mortality rates was not so great as in some of the other diseases, such as tuberculosis, syphilis and malaria, the consistent difference tended to show that rheumatic fever and heart diseases were unfavorably influenced by the adverse social and economic conditions of the nonwhite group. The significantly higher mortality rate among nonwhite girls as compared with white girls in the early childbearing period (15 to 19 years) was assumed to be due to a difference in fertility in the two groups.

Definite regional variations in mortality from acute rheumatic fever occurred among the geographic divisions of the United States. Rates were below average in the South, while in the Northeast, especially in the middle Atlantic division, they were considerably above average. Mortality rates in the Pacific division were comparable with rates in the South; however, in the Mountain division, rates were exceptionally high for children in all age groups. The average death rate in all states was 11.7 per 100,000. This varied from 5.3 in Vermont to 22.4 in Utah.

A prime motive of the study was to obtain practical and detailed information for determining where preventive efforts must be intensified. As acute rheumatic fever is not generally a reportable disease, any efficient campaign against rheumatic fever demands that it be made reportable.

The prospect for longevity in children with rheumatic fever was recently discussed by Wilson and Lubschez.[2] The records of 1,042 children with rheumatic fever were reviewed for a thirty year period (1916 to 1947). In this group the mean age at onset was 6.5 years; this analysis did not reveal any specific age or sex difference. The over-all death rate was 14.7 per thousand per year. An afflicted child had 4 out of 5 chances to survive fifteen years, 3 out of 4 to survive twenty years and 2 out of 3 to survive thirty years after the onset of the disease. A child had a 50 per cent chance to survive to the age of 40. This sample was considered representative of rheumatic children living in the New York city area.

The great present difficulty in rheumatic heart disease is the absence of good, simple, preventive measures or specific methods of treatment. A recent study by Weston[3] and the Wolff report[1] suggest that the problem is one for the entire community and that it requires a type of attack similar to that which has been carried out against tuberculosis. Improvement in socioeconomic factors such as improved housing, elimination of overcrowding, better nutrition and routine preschool and school examination to detect early cases should bring notable decrease both in incidence and severity of the disease.

POLIOMYELITIS PORTAL OF ENTRY

Doubt of the validity of the concept that the gastrointestinal tract is the usual portal of entry for poliomyelitis virus is expressed by Faber[1] and his associates of the Department of Pediatrics, Stanford University, as a result of inoculation experiments on cynomolgus monkeys. In their first series of tests, poliomyelitis virus (*Per* strain) was enclosed in crisco®-coated gelatin capsules and introduced by means of a curved metal cannula into the stomachs of 26 unanesthetized monkeys. None of these animals contracted poliomyelitis. Sabin and Ward[2] had previously found that the same virus administered by simple feeding, which involves simultaneous exposure of both the pharyngeal and gastrointestinal surfaces, induced infection in 40 per cent of their monkeys. Faber's negative results therefore suggest that as compared to the oropharyngeal surfaces the gastrointestinal mucosa is relatively impervious to the virus.

In a second series of tests, 18 cynomolgus monkeys were fed with repeated massive doses of the more highly virulent *Cam* strain by the same technic. The capsules were given before the morning meal on three successive days. In only 1 of the 18 monkeys thus fed did poliomyelitis develop. Of the 6 control monkeys fed the same virus, mixed with their regular diet, 3, or 50 per cent, succumbed to the disease.

In each of the capsule-fed animals, virus appeared in the stools during and immediately after the feeding periods. The virus disappeared thereafter from all stools except in the 1 case in which the infection developed. The inference was drawn that the intestinal epithelium is not a suitable host for the multiplication of this virus. No evidence of resistance to intracerebral inoculation was noted in subsequent tests of the seventeen uninfected capsule-fed animals.

These results are in accord with the belief that poliomyelitis enters primarily through superficial nerve endings. Histologic studies have shown[3] that nerve fibers do not penetrate further than the subepithelial level of the gastrointestinal tract. In certain parts of the pharynx and mouth the nerve fibers actually penetrate to the surface between the epithelial cells.[4] Conceivably the 1 capsule-fed monkey that contracted poliomyelitis did so as a result of secondary contamination with its own infected stools.

Current Comment

EXUDATIVE PLEURISY IN CHILDREN

From the Pediatric Clinic of Karolinska Institutet at Norrtull's Hospital, Stockholm, and the State Institute of Human Genetics and Race Biology, Uppsala, Nathhorst[1] investigated 595 children up to 16 years of age who had been treated at the children's hospitals in Göteborg and Stockholm for exudative pleurisy. As a control series, 575 healthy tuberculin-positive children of comparable age from the children's home in Göteborg were studied. The mean period of observation was 13.1 and 13.7 years respectively. During hospitalization for pleurisy, 585 of the 595 children were tuberculin positive. In 65 per cent, the onset was acute, and in 35 per cent insidious. The temperature and sedimentation rates were the same whether onset was acute or not. An infection of the upper respiratory tract did not seem to be of any specific importance in causing pleurisy in those who fell ill during hospitalization. Boys showed a higher incidence of pleurisy than girls. The risk for a boy up to 15 years of age in Göteborg is 9.3 per thousand and for a girl, 6.0 per thousand. The risk is greatest from March to May and least from August to October. The mortality of parents of pleuritic children from tuberculosis was 6.2 per cent in contrast to 3.3 per cent mortality for the general population. This is attributed to hereditary factors and infection in which the parents play a role. In only 53 of 538 cases was contagion established; in most, the source of exposure was unknown. Of 595 in the pleurisy series, 53 later died of tuberculosis, 28 of these from pulmonary tuberculosis. Compared with the urban population, there should have been only 10 deaths, whereas the risk of death from nontuberculous diseases was found to be the same in the two series. The risk of death from tuberculosis is greatest during the first year of observation in the pleurisy series—viz., 2.4 per cent (all of these dying from extrapulmonary tuberculosis)—then remaining fairly constant until about the tenth year of observation, and later decreasing slightly; from the sixteenth to the twentieth year of observation, the annual mean risk is 0.34 per cent and nearly twice that of the population. The risk of death is higher in the children who contract pleurisy at 10 to 16 years of age as compared with those who fall ill at ages 0 to 9 years. This is due to the fact that while the mortality from extrapulmonary tuberculosis is roughly the same in both groups, the mortality from pulmonary tuberculosis is higher in the older children. One would expect the morbidity to run parallel to the mortality, though the reports in this respect are not quite reliable. The risk of subsequently contracting tuberculosis during the first five years of observation is somewhat greater in those children whose pleurisy was preceded by a tuberculous manifestation such as erythema nodosum or hilar adenitis. The course of the onset or the size of the exudate does not seem to be of importance in the late prognosis. In 78 per cent, the roentgenogram taken during treatment for pleurisy showed a tuberculous primary pulmonary infection which was supraclavicularly located in 11 per cent. In 92 per cent of the cases, it was on the same side as the pleurisy. More than five years after the pleurisy in 57 per cent, foci of calcification in hilus or pulmonary parenchyma were present. In most cases there are adhesions between the pleural leaves. Out of 30 pneumothorax interventions on the same side as the pleurisy, the intervention was unsuccessful in 26 cases and a complete success in 2 cases only. Rheumatic fever was uncommon in both series; in the pleurisy series, only 0.7 per cent, and in the controls, 1.9 per cent. Such a study should be duplicated in other surroundings and under other conditions, though its major findings and application generally appear of value.

THE SUPPLY OF PHYSICIANS TO THE ARMED FORCES

Medical officers now on duty with the armed forces who will soon complete two years of active duty following A.S.T.P. or V-12 training are disturbed by the possibility that they may be retained in the services if the present campaign to stimulate voluntary entry on active duty of A.S.T.P. and V-12 graduates, with little or no active military duty, fails. If the needs of the armed forces cannot be met by voluntary medical officer recruitment, only two alternatives will remain: a compulsory draft of A.S.T.P. and V-12 doctors without military service or postponement of the release of medical officers now on active duty. The latter step, although legally justifiable according to the interpretation of the Judge Advocate Generals of the Army and Navy, would be a violation of a moral obligation to accept two years' service in return for government sponsored and supported training. Faced by these alternatives, a draft for those who have never served or the retention of those who have, the American Medical Association will no doubt urge the calling up of those who have not served.

ORGANIZATION SECTION

NOTICE TO PHYSICIAN-ARTISTS

If you plan to exhibit at the Atlantic City Exhibition (American Medical Association, June 6-10, 1949) now is the time to write for entry blanks, rules, shipping labels, etc. Haste is necessary because your entries must reach Atlantic City between April 15 and May 9.

For details, please write air mail to Francis H. Redewill, M.D., Secretary, American Physicians Art Association, Flood Building, San Francisco, Calif.

Medical Legislation

STATE LEGISLATION

Arizona

Bill Introduced.—H. 176 proposes to direct the governor to appoint a state **board of examiners for practical nurses** and proposes further that no practical nurse certified by this board shall engage in the following procedures unless under the direct instruction and supervision of a licensed physician: (1) administration of intravenous or intramuscular injections; (2) practice of oxygen, carbon dioxide or other gas therapy; (3) administration of anesthetics; (4) gavaging or lavaging; (5) catheterization or irrigation of the bladder; (6) taking of blood pressure, and (7) computation of dosage of medicine.

Arkansas

Bills Introduced.—H. 363 requires the **committee on admissions of the School of Medicine** of the University of Arkansas to allocate position vacancies in the school by congressional districts based on the population of each district. S. 230 proposes the repeal of the **basic science law.**

California

Bills Introduced.—A. 2171, to amend the motor vehicle act, proposes that the term "physician" as used therein shall include a licensed **doctor of chiropractic**, thus authorizing chiropractors to obtain the special insignia approved by the Department of Motor Vehicles indicating that the vehicle is owned by a licensed physician. A. 2172, to amend the labor code, proposes to authorize the **Industrial Accident Commission** to adopt and enforce fee schedules for persons authorized to render services to injured employees. A. 2257, to amend the health and safety code, proposes that no person shall be excluded from a hospital maintained by a hospital district because his attending physician and surgeon is a member of a **particular school of practice**, so long as such physician and surgeon is licensed under the provisions of Chapter 5, Division 2 of the Business and Professions Code. A. 2417, to amend the health and safety code relating to the state board of public health, proposes that one member of such board shall be a duly licensed and **practicing chiropractor.** A. 2690 proposes the creation of a **board of practical nurse examiners** and defines practical nursing as the performance of such nursing duties as are required in the physical care of a patient in carrying out of medical orders as prescribed by a licensed physician, requiring an understanding of nursing skills, but not requiring the professional nursing services as defined in the Nursing Practice Act. S. 1374, to amend the health and safety code, proposes that no person shall furnish any **hypnotic drug** unless it is administered by a physician, dentist, chiropodist or veterinarian. S. 1424, to amend the health and safety code, proposes the establishment of an advisory **chronic disease council** to conduct a program directed toward the reduction of deaths and disability from cancer and other chronic diseases.

New York

Bills Introduced.—A. 1198, to amend the law relating to **narcotic drugs**, proposes that the term "physician" shall include osteopaths. A. 1233 proposes an appropriation of $50,000 to defray the cost of studies and researches into the causes of **the common cold**, designed to prevent, control and cure such diseases. A. 1302, A. 1579 and S. 1258 propose the establishment of a **school of medicine** in the county of the Bronx. A. 1397 proposes the enactment of a comprehensive system of **health insurance.** A. 1399 and S. 1254 propose the creation of a commission to make a comprehensive study and survey of the causes and **effects of heart disease**, *rheumatic fever, rheumatic heart and kindred or* related diseases, of existing methods and facilities for the treatment of persons suffering therefrom, to formulate a long range program for continuing researches into and more effective methods and means for the prevention, treatment and cure of such cases. A. 1407, to amend the public health law, proposes to require physicians to notify immediately the health officer of the county, city, town or village wherein such person resides of every case of **infantile paralysis** under his care. A. 1644 proposes the creation of a board of **medical technologist** examiners and defines medical technology as the science, art or technic of performing microscopic examinations, chemical tests, chemical analyses, colorimetric comparison tests, the culture of pathogenic bacteria on or from the blood, blood serum, feces, urine, sputum, exudates, transudates, tissues, organ contents, or any by-products thereof, from the human body, living or deceased; when the tests shall be used either directly or indirectly as an aid in diagnosis or to aid in confirming a diagnosis, or to aid in the care or treatment of diseased, abnormal or injured organs of the human body. A. 1653 proposes to require a physician in attendance at birth to immediately cause the **footprints of the newborn child** and the thumbprints of the mother of such child to be taken and forthwith delivered to the mother. S. Res. 64 proposes that the state department of health be memorialized to do everyhing in its power to stimulate, encourage and provide aid to local hospitals and clinics to set up and maintain outpatient clinics qualified to treat children suffering from **cerebral palsy**, such hospitals to meet standards set up by the commissioner of health and to contract with such local institutions so qualified for research in the causes, diagnosis, treatment and cure of cerebral palsy. S. Res. 68 proposes that the state department of health be memorialized to select a group of licensed physicians and accredited physiotherapists, occupational therapists, speech therapists and public health nurses to be trained at the expense of the state as **specialists in cerebral palsy** at centers within or without the state, recognized and established as centers for the training of such personnel. S. 1180, to amend the education law, proposes to make it the duty of each medical inspector having jurisdiction over any public school in the state to examine each pupil attending such school for **symptoms of tuberculosis** at least once each school year. S. 1447 proposes to make it the duty of every householder before employing any person for domestic services to require from such person the production and surrender of a certificate of good health from a duly licensed and registered physician certifying that such person is **free from tuberculosis**, any venereal disease in its communicable or infectious stage or any other infectious, contagious or communicable disease. S. 1465, to amend the law relating to prenatal tests, proposes to require physicians to make serologic blood tests for the **Rh factor** of all pregnant women. S. 1511 proposes the enactment of a **disability compensation law.** S. 1712 proposes to prohibit the **sale of benzedrine** in penal institutions.

Oregon

Bills Introduced.—S. 213, to amend **the osteopathic act**, proposes that the practice of osteopathy and surgery by a duly appointed member of the resident staff or by an intern while actually serving as such in any legally incorporated osteopathic hospital shall not be governed by the act. The proposal would also authorize the board of osteopathic examiners to accept a certificate of successful examination issued by the National Board of Examiners of Osteopathic Physicians and Surgeons in lieu of its own examination. S. 233 proposes that no person shall furnish any dangerous drug except on the prescription of a physician, dentist, chiropodist or veterinarian. **"Dangerous drug"** is defined to include any hypnotic drug (acetylurea derivatives, barbituric acid or malonylurea derivatives, chloral, paraldehyde, phenylhydanton derivatives, sulfonmethane derivatives or any compounds or mixtures thereof), aminopyrine, amphetamine, cinchophen, diethylstilbestrol, ergot, oils of croton, sulfanilamide or substituted sulfanilamides or mixtures thereof, all glandular preparations except insulin and liver preparations, phenol. S. 239 proposes to provide for the promotion of medical science by the distribution and use of **unclaimed human bodies** for scientific purposes by the University of Oregon Medical School.

South Dakota

Bills Introduced.—H. 171 proposes to authorize the state nurses examining board to examine and grant licenses for the **practice of practical nursing.** A licensed practical nurse is defined as a person authorized under this act to perform for compensation such duties as are required in the physical care of a convalescent, a chronically ill, aged or infirm patient, and in carrying out such medical orders as are prescribed by a duly licensed physician, requiring a knowledge of simple nursing procedures, but not requiring the professional knowledge and skill requisite for a registered nurse, and serving in hospitals or elsewhere under the direction of a duly licensed physician or registered nurse. H. 199 proposes general amendments to **the medical practice act.** Among other things the practice is to be controlled by the state board of medical examiners rather than the state board of health and the proposal would require two doctors of osteopathy to be appointed to the five man board of medical examiners. Osteopaths and physicians are joined together all the way through the act and the board is authorized to grant a license to practice medicine, osteopathic medicine, surgery and obstetrics and all other branches without limitations to applicants who pass the examination. S. 167 proposes to authorize **cooperative associations** to be organized for the construction and operation of hospitals and medical clinics.

Tennessee

Bill Introduced.—H. 330 proposes the creation of a **cancer control division** in the Department of Public Health to promote a program for the prevention of cancer within the state.

Utah

Bills Introduced.—H. R. 4 proposes to memorialize the Congress of the United States to pass legislation introduced into the Congress which provides for prepaid medicine or **national health insurance.** H. 204, to amend the law relating to **premarital examinations**, proposes to authorize osteopaths and naturopaths to furnish the required physical certificates.

Bills Enacted.—S. Res. 4 was approved February 11. It memorializes the Congress of the United States to defeat any legislation introduced into Congress which provides for **socialized medicine or national compulsory health insurance** and which will result in a destruction of private initiative and the free enterprise system in this country and that Congress be urged to restrict its legislation to measures which will encourage private health insurance in cooperation with the private practice of medicine. S. 30 was approved February 17. It provides for the creation of a **State Board on Alcoholism** *to investigate the causes of alcoholics and alcoholism and to cooperate* with the Utah State Committee for Education on Alcoholism and Alcoholics Anonymous.

Washington Letter

(From a Special Correspondent)

Feb. 21, 1949.

Florida Representative Sponsors Education Subsidy Bills

Rep. George A. Smathers (Democrat, Florida) has become the sponsor of legislation whose ultimate goal is to increase the country's supply of physicians and dentists. In late January he introduced bills (H. R. 1779 and H. R. 2045) providing for federal loans to medical students and grants-in-aid for expansion of existing medical schools and construction of new ones. Early in February he filed two more bills (H. R. 2524 and H. R. 2525) which would do the same for dental education. All four measures are under consideration by the House Committee on Education and Labor.

A native of New Jersey who moved to Florida as a child, Representative Smathers is one of the youngest members of Congress (aged 35) and has taken a prominent role in support of health and medical legislation ever since he took his seat in Congress two years ago.

Dental Goods Conspiracy Charged by Federal Trade Commission

Conspiracy to eliminate competition in manufacture and distribution of dental goods is charged in a Federal Trade Commission complaint filed against 144 makers and suppliers, the American Dental Trade Association and its officers. According to the Commission, the respondents are located in all but twelve of the forty-eight states and are responsible for more than three fourths of the dental goods distributed in the United States. Among them are Wilmot Castle Company, American Sterilizer Company, Johnson & Johnson and General Electric X-ray Corporation. The complaint was made public and respondents are allowed twenty days to answer the charges. Dental goods involved are all articles used in the practice of dentistry, including chairs and office furniture as well as artificial teeth, instruments, alloys, drugs and compounds.

The companies and individuals cited are accused of having violated the Federal Trade Commission Act by conspiring to regulate competition. Effect of their allegedly collusive practices is "to control the market and enhance the prices paid by purchasers." Such practices, said the Federal Trade Commission complaint, "have a dangerous tendency to create monopoly."

Among the specific charges are that the respondents: classified dental goods and agreed on exact retail prices at which the various classifications should be sold both to dealers and the ultimate consumers; agreed on uniform rates of discount and uniform terms of credit; agreed on a division of territory among the various member dealers; established a plan of "policing the industry," and prevented nonmembers of the trade association from obtaining merchandise for resale.

Anticompulsion Editorial Printed in *Record*

An editorial that appeared in the Richmond (Ind.) *Palladium-Item*, recommending that this country not adopt the British system of sickness insurance, was printed in the *Congressional Record* for February 7 under sponsorship of Rep. Ralph Harvey (Republican, Indiana).

"Our taxpayers should know by now that nothing they get from the Government ever is free. Sooner or later they themselves foot the bill. And this will be true of national health insurance. The Government has no business in this field. Britain's muddling around should be evidence enough."

Coming Medical Meetings

Alabama, Medical Association of the State of, Montgomery, April 19-21. Dr. Douglas L. Cannon, 519 Dexter Ave., Montgomery 4, Secretary.

American Association for Thoracic Surgery, New Orleans, March 29-31. Dr. Brian Blades, George Washington University Hospital, Washington, D. C., Secretary.

American Association of Anatomists, Philadelphia, April 13-15. Dr. Normand L. Hoerr, 2109 Adelbert Road, Cleveland 6, Secretary.

American Association of Industrial Physicians and Surgeons, Detroit, Book-Cadillac and Statler Hotels, April 5-9. Dr. Edward C. Holmblad, 28 E. Jackson Blvd., Chicago 4, Managing Director.

American Association of Pathologists and Bacteriologists, Boston, April 15-16. Dr. Howard T. Karsner, 2085 Adelbert Road, Cleveland, Secretary.

American Association on Mental Deficiency, New Orleans, Hotel Roosevelt, April 27-30. Dr. Neil A. Dayton, Box 51, Mansfield Depot, Conn., Secretary.

American Broncho-Esophagological Association, Chicago, Drake Hotel, April 18-19. Dr. Edwin N. Broyles, 1100 N. Charles St., Baltimore 1, Secretary.

American College of Allergists, Chicago, April 14-17. Dr. Fred W. Wittich, 423 LaSalle Medical Bldg., Minneapolis 2, Secretary.

American College of Physicians, New York, March 28-April 1. Dr. George Morris Piersol, 4200 Pine St., Philadelphia 4. Secretary General.

American Industrial Hygiene Association, Detroit, Book-Cadillac and Statler Hotels, April 5-7. Dr. Henry F. Smyth Jr., 4400 Fifth Ave., Pittsburgh 13, Executive Secretary.

American Laryngological, Rhinological and Otological Society, Chicago, Drake Hotel, April 18-20. Dr. C. Stewart Nash, 277 Alexander St., Rochester 7, New York, Secretary.

American Orthopsychiatric Association, Chicago, Stevens Hotel, April 4-6. Nina Ridenour, Ph.D., 25 W. 54th St., New York 19, Secretary.

American Pediatric Society, Atlantic City, May 5-6. Dr. Henry G. Poncher, 1819 W. Polk St., Chicago 12, Secretary.

American Physiological Society, Detroit, April 19-22. Dr. Milton O. Lee, 2101 Constitution Ave., Washington 25, D. C., Executive Secretary.

American Society for Clinical Investigation, Atlantic City, May 2. Dr. Paul B. Beeson, Grady Hospital, Atlanta 3, Georgia, Secretary.

American Society for Experimental Pathology, Detroit, April 18-22. Dr. Frieda S. Robscheit-Robbins, 260 Crittenden Blvd., Rochester, N. Y., Secretary.

American Society for Pharmacology and Experimental Therapeutics, Detroit, April 18-22. Dr. Harvey B. Haag, Medical College of Virginia, Richmond 19, Secretary.

American Society for Research in Psychomatic Problems, Atlantic City, Chalfonte-Haddon Hall, April 30-May 1. Dr. Sydney G. Margolis, 714 Madison Ave., New York 24, Executive Secretary.

American Society of Biological Chemists, Detroit, April 17-22. Dr. Otto A. Bessey, 1853 W. Polk St., Chicago 12, Secretary.

American Surgical Association, St. Louis, April 20-22. Dr. Nathan Womack, University of Iowa, Iowa City, Secretary.

Arkansas Medical Society, Little Rock, April 14-16. Dr. William R. Brooksher, 602 Garrison Ave., Fort Smith, Secretary.

Association of American Physicians, Atlantic City, May 3-4. Dr. Henry M. Thomas Jr., 1201 N. Calvert St., Baltimore 2, Secretary.

Connecticut State Medical Society, New Britain, State Teachers' College, May 3-5. Dr. Creighton Barker, 258 Church St., New Haven, Secretary.

Dallas Southern Clinical Society, Dallas, Texas, March 14-17. Miss Thelma Webb, 1133 Medical Arts Bldg., Dallas, Executive Secretary.

Federation of American Societies for Experimental Biology, Detroit, April 18-22. Dr. Milton O. Lee, 2101 Constitution Ave., Washington 25, D. C., Secretary.

Iowa State Medical Society, Des Moines, April 18-21. Dr. Allan B. Phillips, 406 Sixth Ave., Des Moines 9, Secretary.

Louisiana State Medical Society, New Orleans, May 5-7. Dr. P. T. T. Talbot, 1430 Tulane Avenue, New Orleans 13, Secretary.

Maryland, Medical and Chirurgical Faculty of the State of, Baltimore, April 26-27. Dr. George H. Yeager, 1211 Cathedral St., Baltimore 1, Secretary.

Michigan Postgraduate Clinical Institute, Detroit, Book-Cadillac Hotel, March 23-25. Dr. L. Fernald Foster, 2020 Olds Tower, Lansing 8, Mich., Secretary.

Missouri State Medical Association, Kansas City, March 27-30. Mr. T. R. O'Brien, 634 N. Grand Blvd., St. Louis 3, Secretary.

National Tuberculosis Association, Detroit, May 2-6. Dr. H. Stuart Willis, 1790 Broadway, New York 19, Secretary.

Nebraska State Medical Association, Omaha, Hotel Paxton, May 2-5. Dr. R. B. Adams, 416 Federal Securities Building, Lincoln 8, Nebraska, Secretary.

New Jersey, Medical Society of, Atlantic City, Hotel Ambassador, April 25-28. Dr. Earl L. Wood, 315 W. State St., Trenton 8, Secretary.

New Mexico Medical Society, Roswell, May 5-7. Dr. H. L. January, 221 W. Central Ave., Albuquerque, Secretary.

New York, Medical Society of the State of, Buffalo, Hotel Statler, May 2-6. Dr. Walter P. Anderton, 292 Madison Ave., New York 17, Secretary.

Ohio State Medical Association, Columbus, April 19-21. Mr. Charles S. Nelson, 19 E. State St., Columbus 15, Executive Secretary.

Southern Branch, American Public Health Association, Dallas, Texas, Baker Hotel, April 14-16. Dr. George A. Denison, 600 S. Twentieth St., Birmingham, Ala., Secretary.

Southwest Allergy Forum, El Paso, Texas, Hotel Paso del Norte, April 4-5. Dr. O. E. Egbert, First National Bank Bldg., El Paso, Secretary.

Tennessee State Medical Association, Chattanooga, April 12-14. Dr. W. M. Hardy, 706 Church Street, Nashville 3, Secretary.

Texas, State Medical Association of, San Antonio, May 2-5. Dr. Harold Williams, 700 Guadalupe St., Austin, Secretary.

GOVERNMENT SERVICES

SECRETARY OF DEFENSE

COMMITTEE TO ADVISE ARMED FORCES

Secretary of Defense Forrestal has announced the appointment of a committee which will advise the armed forces on medical policies and programs. The members of this committee, which will succeed the Hawley Committee, are Charles P. Cooper, president, Board of Trustees, Presbyterian Hospital, New York, chairman; Drs. Maurice C. Pincoffs, Baltimore; Edward D. Churchill, Boston; Richard L. Meiling, Columbus, Ohio; Howard A. Rusk, New York; Paul Titus, Pittsburgh; Paul Hawley, Chicago; Michael DeBakey, Houston, Texas; Raymond B. Allen, Seattle, Wash.; Walter H. Schere, D.D.S., Houston, Texas, and the three surgeons general.

ARMY

WOMEN'S MEDICAL SPECIALIST CORPS

Training courses to qualify applicants for appointment in the Women's Medical Specialist Corps of the Regular Army will be offered beginning in September 1949. The training program will include a dietetic internship, a physical therapy training course and an occupational therapy clinical affiliation. The dietetic internship will consist of both didactic instruction and practical application. The physical therapy training course will include two phases of about six months each. The first phase, conducted at the Brooke Army Medical Center, Fort Sam Houston, Texas, will be primarily didactic instruction. During the second phase, students will be assigned to selected Army general hospitals for further instruction and supervised clinical practice. The occupational therapy clinical program will be conducted in Army general hospitals where well organized occupational therapy programs are in progress. Prior to beginning this training, students will be required to complete a two months' basic training course at the Brooke Army Medical Center.

Applicants must meet the following qualifications: (1) dietetic internship—a bachelor of science degree from a college or university approved by the Surgeon General, with a major in either foods and nutrition or in institutional management; (2) physical therapy training course—a baccalaureate degree from a college or university approved by the Surgeon General, with major emphasis on physical education or the biologic sciences, or (3) occupational therapy clinical affiliation—a baccalaureate degree and the first year of a two-year course in occupational therapy, or completion of four years (120 semester hours) leading to such a degree in a college or university approved by the Surgeon General.

Participation in this program is available only to unmarried women who have no dependents under 18 years of age. An applicant must be a citizen of the United States, and must have passed her twenty-first birthday but not have passed her twenty-sixth birthday on the date of appointment. Applicants must meet the physical requirements as prescribed in Army Regulations for appointment in the Women's Medical Specialist Corps. Persons selected must agree to apply for commissions as second lieutenants in the officer's reserve corps and volunteer for two years of extended active duty, which includes the entire period of training.

Persons appointed in the Women's Medical Specialist Corps Section of the officers' reserve corps will be called to extended active duty in the grade of second lieutenant and will be paid $180 a month in addition to 70 cents a day toward subsistence. They will be provided with government quarters and will have equal status with all Army officers of comparable grade.

Application blanks may be obtained from the Surgeon General, U. S. Army, Washington 25, D. C., Attention, Women's Medical Specialist Corps.

PUBLIC HEALTH SERVICE

RESEARCH IN MILK AND FOOD SANITATION

Dr. W. Palmer Dearing, Deputy Surgeon General, welcomed two hundred researchers from all parts of the country to a symposium, January 26-27, on research in milk and food sanitation, sponsored by the National Institutes of Health. Dr. Dearing said, "We understand the epidemiology of typhoid, dysenteries, salmonellosis and other diseases for which milk and food are known to be the vehicles of infection. No such knowledge exists about gastroenteritis of unknown etiology. The role of sanitation in diseases not obviously related to the gastrointestinal tract has scarcely been explored. Recently work on nutrition and vital resistance in mice may have important implications in food sanitation. In a different area, we do not yet know much about the administration of milk control, or its economic implications. It is evident there are major, untouched problems in this field." At the four sessions of the symposium, the presiding officers were: Mr. V. M. Ehlers, director, Bureau of Sanitary Engineering, Texas State Department of Health; Dr. W. L. Mallmann, professor of bacteriology and public health, Michigan State College; Major Raymond J. Karpen, sanitary engineer, Environmental Sanitation Branch, Office of the Surgeon General, Department of the Army, and Dr. F. C. Bishopp, assistant chief in charge of research, Bureau of Entomology and Plant Quarantine, Department of Agriculture.

MEETING ON VENEREAL DISEASE RESEARCH

A joint meeting on venereal disease research will be held in Washington, D. C., April 7-8, and the program on the first day will be a symposium on recent advances in the study of venereal diseases under the auspices of the Syphilis Study Section of the National Institutes of Health. On the second day will be held the annual scientific session of the American Venereal Disease Association. Both day meetings will be in Room 1517, Federal Security Building North, Washington, D. C. All persons interested are invited to attend, and copies of the program will be sent on request. Inquiries should be addressed to Dr. William L. Fleming, Secretary, American Venereal Disease Association, 750 Harrison Avenue, Boston, or to the Executive Secretary, Syphilis Study Section, National Institutes of Health, Bethesda, Md.

EXAMINATION FOR THE REGULAR CORPS

A competitive examination for appointment of medical officers in the Regular Corps of the U. S. Public Health Service will be held May 3-5. The appointments are in the grades of assistant surgeon (first lieut.), and senior assistant surgeon (captain). Examinations will be held at Baltimore, New Orleans, San Francisco, Seattle, Chicago, Cleveland, Detroit, Boston, Memphis, Los Angeles, Denver, Atlanta, Ga., Kansas City, Mo., Lexington, Ky., Kirkwood, Mo., and Staten Island, N. Y. Applicants must be citizens of the United States, at least 21 years of age and graduates of a recognized medical school. Appointment for the grade of senior assistant surgeon requires also at least ten years of educational training and professional experience subsequent to high school. The entrance pay is $5,011 per annum and $5,689 respectively for officers with dependents. Promotions are made at regular intervals up to the grade of senior surgeon. Retirement pay after thirty years of service is $4,950 per year. Application forms can be had from the Surgeon General, United States Public Health Service, Washington 25, D. C. Applications must be completed by April 4.

COMMITTEE ON HABIT-FORMING DRUGS

Dr. Nathan B. Eddy has been elected chairman of the Expert Committee on Habit-Forming Drugs of the World Health Organization. The committee is now in session at Geneva, Switzerland, considering whether new synthetic analgesics can be defined as addicting drugs and are therefore subject to international control. Dr. Eddy, a native of New York, is a graduate of Cornell University Medical College, a former practitioner of medicine, instructor in physiology at McGill University, assistant professor in physiology and pharmacology at the University of Alberta and research professor of pharmacology at the University of Michigan. The other members of the committee are Dr. J. R. Nichols, British Government chemist of London, England; Dr. P. O. Wolff of Buenos Aires, Argentina; Professor J. Bouquet of Tunis, and Professor H. P. Chu of the National College of Medicine at Shanghai, China.

SOUTH AMERICAN ASSIGNMENTS

Nicholas G. Barbella, biochemist, and John V. Yates, laboratory assistant, have gone to Lima, Peru, for research on the cocoa leaf chewing habit among the natives of that country. The Peruvian Government last year proposed a Commission of Inquiry by the United Nations info the cocoa leaf chewing habit. The project which is now under way is a cooperative project between the United States Public Health Service and the Institute of Andean Biology, which is connected with the medical faculty of Lima, Peru.

F. Carlyle Roverts, sanitary engineer, a commissioned officer of the Pan-American Sanitary Bureau, is on duty in South America, detailed to the Bahia State Health Department of Brazil to study water supply and sewage disposal facilities and other sanitation problems in the interior of the State of Bahia.

ESTIMATE OF NUMBER OF HOSPITAL BEDS NEEDED

The plans for hospital construction submitted by the various states and territories (exclusive of Nevada which has not yet submitted a plan) show that there are now a total of 1,024,840 hospital beds, of which 879,527 are considered acceptable by the state and territorial agencies. The others are unacceptable, the U. S. Public Health Service announces, because of fire hazards, unsuitable design or other failure to meet the standards set up by the agencies administering the program. The states and territories estimate, on the basis of standards set forth in the Federal Hospital Survey and Construction Act, that an additional 897,146 hospital beds are needed. The nation has, according to the state plans, 397,168 acceptable beds for general hospital care and needs an additional 255,443 beds. The nation has a total of 381,627 acceptable beds in mental hospitals and requires, it is estimated, 310,523 additional beds in this category. Beds in institutions for mental deficiencies and epilepsy are not considered in the state plans. The nation has 72,215 acceptable beds for tuberculosis hospital care and needs 82,886 more. The so-called chronic hospitals have 28,517 beds and need, it is said, 248,294 additional beds to give adequate care of these patients.

AID TO SCHOOLS FOR UNDERGRADUATE TRAINING IN PSYCHIATRY

At a recent meeting of National Advisory Mental Health Council in Washington, D. C., the award of grants totaling nearly $1,500,000 to forty-two medical schools for expanding or developing undergraduate training in psychiatry was recommended by the Council. In selecting the schools to receive grants, the Council gave favorable weighting to those schools which were not receiving other mental hygiene grants from the government, could not obtain needed funds from other sources, had not been able to establish a strong program but had potentialities for doing so, had a receptive setting in terms of facilities, faculty interest, and appreciation of the importance of psychiatric factors in medical practice. The first funds will be made available for the 1949-1950 school year, and subsequent payments will be in equal allotments for the two following school years. The medical schools which will receive government grants through the U. S. Public Health Service for undergraduate training in psychiatry are:

Medical School	Total Grant for Three Years
Medical College of Alabama	$27,500
Albany Medical College (Albany, N. Y.)	37,500
University of Arkansas	37,500
Baylor University (Houston)	34,976
Dartmouth Medical School	4,500
Emory University (Atlanta)	37,500
George Washington University	37,500
Georgetown University	37,500
Hahnemann Medical College (Philadelphia)	37,500
Howard University	29,697
State University of Iowa	37,179
Jefferson Medical College (Philadelphia)	37,500
Johns Hopkins University	34,992
University of Kansas	37,500
Long Island College of Medicine	37,500
Louisiana State University	37,420
Loyola University (Chicago)	36,180
University of Maryland	30,000
Meharry Medical College (Nashville)	37,463
University of Michigan	32,100
University of Minnesota	37,500
University of Nebraska	37,260
New York University	37,500
Ohio State University	37,500
University of Oklahoma	37,500
Pennsylvania Woman's Medical College (Philadelphia)	37,302
University of Rochester	37,404
Southwestern University (Dallas)	37,500
Syracuse University	37,044
Temple University	37,300
University of Tennessee	37,500
University of Texas	34,000
Tulane University of Louisiana	37,500
University of Utah	37,500
University of Vermont	37,152

MISSION TO LIBERIA

The Mission to Liberia was established in 1944, and when the first public health service personnel arrived in Monrovia in November of that year, very few facilities were available with which to begin operations. Of the improvement brought about since that time, one indication is the increase in money appropriated for public health and medical care by the Liberian Government, from $72,000 in 1944 to $300,000 in 1948. Dr. Hildrus A. Poindexter, who was recently appointed Director of the Liberian Mission, left for Monrovia January 10 to replace Dr. John B. West, resigned, who before leaving that country was awarded the decoration of Vice-Commander of the Order of African Redemption by the Liberian Government in recognition of his work with the Mission. Other personnel who have returned from the Mission for reassignment by the Public Health Service are Thomas Johnson, medical entomologist; Alma Jackson Baynard, health educator, and Lillian Holly and Clara Beverly, nursing arts instructors.

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

ARIZONA

Cerebral Palsy Unit in Phoenix.—A cerebral palsy nursery school has been opened as a project of the Junior League of Phoenix at the suggestion of the National Society for Crippled Children and Adults. The policies of the new school are supervised by a board made up of the Maricopa County Crippled Children's Society and the Cerebral Palsy Parents Council. The county crippled children's society donated equipment and offered professional consultation. In addition to directed play the nursery offers therapeutic care and treatment.

CALIFORNIA

Dr. Mushin Visiting Professor.—Dr. William Mushin will be visiting professor of anesthesiology at Stanford University School of Medicine, Stanford-San Francisco, March 15 to May 15. Dr. Mushin in professor of anesthesiology at both the University of Wales and the Royal College of Surgeons of England.

Langley Porter Clinic.—The University of California Langley Porter Clinic has established a department of neurosurgery and a comprehensive research program on the problem of brain surgery in psychiatric treatment. The clinic's surgical service, which does not include the usual neurosurgery, will be devoted to treatment of cases involving peculiar mental conditions.

FLORIDA

Seminar on Diabetes.—A seminar on diabetes will be held at the George Washington Hotel, Jacksonville, March 28-29 in cooperation with the department of medicine of the Graduate School of the University of Florida, the Clinical Society of the Duval County Diabetes Association and the U. S. Public Health Service. The speakers will be Drs. Charles H. Best, Toronto, Canada; Elliott P. Joslin, Boston; Joseph H. Barach, Pittsburgh, and John A. Reed, Washington, D. C. There will be no registration fee. Hotel reservations may be made through Dr. Malcolm J. Ford, Diabetes Demonstration Unit, Box 210, Jacksonville.

ILLINOIS

Chickenpox.—The state department of public health states that 400 to 500 cases of chickenpox were reported weekly during January. The total number of cases reported for 1948 was 15,769, the largest number since 1944, when 16,498 cases were reported. Three deaths from chickenpox were recorded in Illinois in 1947.

Chicago

Lecture on Nutrition.—Dr. Frederick J. Stare, Harvard Medical School, Boston, will speak on "Calories in Parenteral Nutrition" at a meeting of the Chicago Nutrition Association March 25 in the English Room II, Marshall Field & Company, at 12 noon. Dr. Stare has been editor of *Nutrition Reviews* since its first issue in 1942.

The McArthur Lecture.—The twenty-fifth Lewis Linn McArthur Lecture of the Frank Billings Foundation of the Institute of Medicine of Chicago will be delivered at the Palmer House March 25 at 8 p. m. by Dr. Warren H. Cole, professor and chairman of the department of surgery, University of Illinois College of Medicine, on "Current Trends in Diseases of the Gallbladder and Bile Ducts."

Society News.—The North Side Branch of the Chicago Medical Society April 7 at the Drake Hotel will hear Drs. Charles B. Huggins, Chicago, speak on "Testicular Tumors" and John D. Camp, University of Minnesota, Minneapolis, on "Significance of Roentgenograms of the Skull in the Diagnosis of Systemic Disease."

Council of Social Agencies Changes Name.—The Chicago Council of Social Agencies has changed its name to "Welfare Council of Metropolitan Chicago" in order to match the name of the organization to the scope of its work. The council now includes more than two hundred health and welfare agencies in the Chicago area in its membership. Mr. Meyer Kestnbaum, president of Hart, Schaffner & Marx, was re-elected president for his fifth annual term. Mrs. William M. Collins Jr. was renamed secretary and Mr. I. S. Loewenberg, treasurer.

INDIANA

State Laboratory Cooperates in Influenza Study.—The laboratory of the Indiana State Board of Health has been named as one of the laboratories cooperating with the U. S. Public Health Service in a plan designed to study possible future epidemics of influenza. The objectives are (1) to identify new strains of influenza virus as they appear and (2) to evaluate their usefulness for incorporation in influenza vaccine. In the event of an outbreak of respiratory disease suspected of being influenzal in nature, regional laboratories throughout the United States will conduct serologic tests to determine the nature of the disease.

Medical School Enrolment Increased.—The State Budget Committee has made a special grant of $116,500 to the Indiana University School of Medicine, Bloomington-Indianapolis, for the specific purpose of expanding its student enrolment. The action is the result of the study of the problem of alleviating the shortage of doctors in Indiana. Careful analysis of its teaching facilities by the university has determined expansion to be feasible. Recommendations were made concerning the cost of remodeling necessary under the proposed enlargement along with employment of a teaching staff and purchase of equipment and supplies. Twenty-one additional students have been admitted to the first year class now totaling 150. A first year class of a similar size will be enrolled during the next year.

MARYLAND

Five Year Study in Obstetrics.—The department of obstetrics of Johns Hopkins Hospital has begun a five year research study to evaluate methods used to control obstetric pain. This study was inaugurated under the codirection of Drs. Louis M. Hellman and Robert A. Hingson, associate professors of obstetrics in the service of Professor Nicholson J. Eastman. Grants to underwrite the cost of this program were given by the Abbott Laboratories, Ciba Pharmaceutical Products, Eli Lilly & Company, Parke, Davis & Company and E. R. Squibb & Sons. Subsequently, collateral grants from the Becton, Dickinson Foundation, Sharp & Dohme, Inc., Winthrop-Stearns Pharmaceutical Company and Merck & Company have been made to augment this program. Johns Hopkins University Medical School and Hospital, United States Public Health Service, the National Institutes of Health and the Sinai Hospital have provided clinical and laboratory facilities for this program, which will include an analysis of results in 20,000 consecutive deliveries during the five year period. Among the studies undertaken in the initial phases of the program are:

1. Effect of air conditioning and humidification on the well-being of mothers and babies.

2. Effect of the systemic analgesics, the general anesthetics and local nerve blocks on the uterine contraction pattern in labor.

3. Arterial and venous oxygen studies on mother and baby with and without influence of pain-relieving drugs.

4. Incidence of maternal and fetal salvage and morbidity in major groups of currently used anesthetic agents.

5. Development and standardization of several new technics in anesthesiology in obstetrics involving new drugs and drug combinations. The program was developed to carry on this study without postgraduate teaching; however, the requests from so many physicians for organized graduate training programs in these technics has required the establishment of a repeating two month course, limited to ten students each.

MICHIGAN

Clinical Institute in Detroit.—The Michigan Postgraduate Clinical Institute of the Michigan State Medical Society will be held at the Book-Cadillac Hotel, Detroit, March 23-25. Among the out-of-state speakers will be:

Howard K. Gray, Rochester, Minn., Surgery of the Biliary Tract.
Harry S. N. Greene, New Haven, Conn., The R. S. Sykes Lecture: Biological Differentiation of Benign and Malignant Tumors.
Chauncey C. Maher, Chicago, Cardiac Care in Thyrotoxicosis.
Leon Schiff, Cincinnati, Differential Diagnosis of Jaundice.
Frank H. Krusen, Rochester, Minn., Practical Uses of Physical Medicine.
L. Howard Schriver, Cincinnati, Political, Social and Economic Problems Facing the Medical Profession.
Frank W. Konzelmann, Atlantic City, N. J., Position of the Laboratory in the Diagnosis and Control of Disease.
Lee Forrest Hill, Des Moines, Ia., Role of the General Practitioner in Child Health Care.
D. W. Gordon Murray, Toronto, Canada, Surgical Repair of Congenital Septal Defects in the Heart and a Surgical Approach to Treatment of Coronary Thrombosis.
Frank L. Meleney, New York, Surgical Treatment of Metastatic Tumors of the Lung.
Howard F. Root, Boston, Medical and Surgical Problems of Diabetes.
F. Bayard Carter, Durham, N. C., Modern Practice of Gynecology.
Francis C. Grant, Philadelphia, Surgical Methods for the Relief of Intractable Pain.

NEW YORK

Virus Laboratory.—A virus laboratory is to be set up by the University of Buffalo at Buffalo General Hospital. To help with its organization Dr. Gilbert Dalldorf, Albany, director of the Division of Laboratories and Research in the state department of health, has accepted appointment as visiting professor of pathology at the medical school.

Postgraduate Instruction.—The Medical Society of the State of New York with the cooperation of the New York State Department of Health has arranged a postgraduate lecture for the Geneva Academy of Medicine at the Belhurst Restaurant in Geneva March 17 at 8:30 p.m. Dr. R. Townley Paton, New York, will speak on "Indications, Contraindications and Technique of Penetrating and Nonpenetrating Corneal Grafts." A series of lectures has been arranged for the Sullivan County Medical Society to be given on Wednesdays at 8:30 p.m.:

March 16, Lenape Hotel, Liberty: Hugh Chaplin, New York, Care and Feeding of Premature Babies.
March 23, Monticello Hospital, Monticello: Gaylord W. Graves, New York, Problems of Practice in the First Year of Life.
March 30, Lenape Hotel, Liberty: Harry Bakwin, New York, Common Behavior Disorders of Children.
April 6, Monticello Hospital, Monticello: Elaine P. Ralli, New York, Diabetes in Childhood.
April 20, Lenape Hotel, Liberty: Rosa Lee Nemir, New York, Pneumonias of Childhood.
April 27, Monticello Hospital, Monticello: Reuel A. Benson, New York, Vaginal Infections in Infants and Childhood.
May 11, Sullivan County Golf and Country Club, Liberty: Charles M. Allaben, Binghamton, Preventive Orthopedics: Common Defects with Good Prognosis Under Medical Care.

New York City

Anniversary Program on Radiation Therapy.—To mark the twenty-fifth year of the establishment of the Radiation Therapy Department at Bellevue Hospital, under the directorship of Dr. Ira I. Kaplan, a series of lectures and clinics will be held March 24 in the Stewart Amphitheatre at the hospital. The speakers in the morning session will be:

Bradley L. Coley, Bone Tumors.
Douglas A. Quick, Advances in Radiation Therapy in 25 Years.
Isidor C. Rubin, Twenty-Five Years' Experience with Irradiation.

Physical and Mental Rehabilitation Convention.—The Association for Physical and Mental Rehabilitation will hold its third annual convention at the Hotel New Yorker, May 18-21. More than five hundred representatives from the nation's Veterans Administration, Army, Navy and Civilian Rehabilitation agencies will be present. Mr. Leo Berner, chief corrective therapist of the Veterans Administration Hospital, is chairman for the convention.

Meetings on Stillbirth and Neonatal Deaths.—The special Committee on Infantile Mortality of the Medical Society of the County of New York has been holding monthly meetings in the Academy of Medicine Building on the third Wednesday of each month at 4 p. m. Physicians, nurses and medical students are welcome. Each meeting is opened with case presentations of stillbirth or neonatal deaths which, in the opinion of members of the committee, were preventable. Remaining lectures are as follows:

March 16, Murray H. Bass, Maternal Contagion Causing Congenital Anomalies in the Newborn.
April 20, Paluel J. Flagg, Resuscitation of the Newborn.
May 18, Ralph L. Barrett, Breech Delivery as a Cause of Neonatal Death.

Dedicate Union Health Center.—The new $3,500,000 Union Health Center of the International Ladies Garment Workers Union, A.F.L., was dedicated February 19 at 275 Seventh Avenue. The center has six floors in the twenty-six story union-owned building. The occasion also marked the thirty-fifth anniversary of the founding of the first center, which operated in one room with one doctor. According to the *New York Times*, the center now has 148 physicians, 33 nurses, 27 technicians, 45 registrars, 5 pharmacists and 150 clerical and maintenance employees. The center last year provided to the members more than 410,000 medical services through twenty-three clinics, seven diagnostic and therapeutic services and five special departments.

Dr. Bernecker Honored.—More than nine hundred representatives of the hospital, health and welfare fields attended a testimonial dinner tendered Dr. Edward M. Bernecker, former commissioner of hospitals, at the Astor Hotel February 28. Dr. Bernecker retired as commissioner of hospitals February 1 and is administrator of hospital services for the New York University-Bellevue Medical Center. Mayor William O'Dwyer was the principal speaker. Among others were Drs. Marcus D. Kogel, successor to Dr. Bernecker; Howard R. Craig, director of the New York Academy of Medicine; Willard C. Rappleye,, dean of the Columbia University College of Physicians and Surgeons, who was Dr. Bernecker's predecessor at the medical center, and Mr. Thomas Pennell, Associated Press reporter who covered the Hospital and Health Building during Dr. Bernecker's tenure of office.

VERMONT

Courses in Epilepsy.—Two courses, each lasting a week, devoted to the study of epilepsy and convulsive disorders are being sponsored by the Vermont Association for the Crippled in cooperation with the University of Vermont College of Medicine, Burlington, and the Vermont State Medical Society. About eight practicing physicians in Vermont are eligible. The course will be held April 18-23. The Vermont Association for the Crippled will defray living expenses by remunerating each man taking the course to the extent of $125. Succeeding courses will be open to all active physicians in the state.

WEST VIRGINIA

Personal.—Dr. Guy R. Post has been confirmed by the Public Health Council as health officer and director of the new Wood-Parkersburg health department at Parkersburg. He is a native of Lewis County and has been located for several years at Clarksdale, Miss., where he has been director of the Coahoma County Health Department. Dr. Post, who will serve full time, assumed his new duties January 1, succeeding Dr. Robert P. Fosnaugh, Parkersburg, who has been serving in a part time capacity.

Association Committee to Confer with Labor Committee.—An advisory committee of three members of the West Virginia State Medical Association has been appointed by Dr. Thomas G. Reed, president, to consult with the three area medical administrators of the United Mine Workers' Health and Welfare Retirement Fund in the state. The committee is composed of Drs. Ray M. Bobbitt, Huntington, chairman; Fred Richmond, Beckley, and John P. Helmick, Fairmont. The area administrators in West Virginia are Drs. John T. Morrison, District 17, Charleston; Lorin E. Kerr Jr., Districts 31, 16 and 4, Morgantown, and Deane F. Brooke, District 29, Beckley.

Relief Doctors.—The chairman of the Council of the West Virginia State Medical Association at a recent meeting was directed to appoint two members to confer with a similar committee from the Public Health Council for the purpose of devising a plan providing for temporary practice by interns and residents in cases where "relief doctors" are needed in any part of the state. It was pointed out by Dr. Newman H. Dyer, Charleston, secretary of the council, that the recent ruling of the attorney general holds that such a proceeding would not be a violation of any part of the state's medical practice act. Subsequently, Drs. T. Maxfield Barber and Russel Kessel, both of Charleston, were named to confer with a committee from the Public Health Council.

Plans for Hospital Construction.—Whitesville, Webster Springs and Franklin with AA priority group rating for hospital construction have made plans to build hospitals without delay. A bond issue of $150,000 has been voted by the citizens of Webster Springs to match available federal funds for construction of a thirty bed hospital. Franklin has applied for federal funds for a community health clinic of fifteen beds, and Whitesville has selected a hospital site and employed an architect to draw plans for a hundred bed general hospital. Preliminary plans have been approved to the final working state for the construction of the first unit of the Charleston Memorial Hospital. Federal and local funds total $3,000,000. To assist small communities in West Virginia to construct hospital facilities and to match federal funds for this purpose, the state department of health has included in its budget a request for $1,000,000 annually for a two year period. The five remaining communities in the AA priority group, Chester, Weirton, Petersburg, Grantsville and Pt. Pleasant, have not yet applied for funds to participate in the hospital construction program.

PHILIPPINES

Philippine Association Desires Medical Publications.—The Philippine Medical Association is seeking donations of medical publications from institutions in the United States to help the medical profession on the islands. Libraries of the members of the association were destroyed during the last war and physicians have been without access to medical literature. All those willing to contribute should communicate with Antonio S. Fernando, M.D., secretary-treasurer, Philippine Medical Association, in care of the Philippine General Hospital, Manila. The association is willing to defray expenses of transportation. Rush Medical College, Chicago, is donating about 1,000 pounds of medical publications.

GENERAL

Meeting of Anesthesiologists.—The Southeastern Section of the American Society of Anesthesiologists will hold its annual meeting April 7-9 at the Statler Hotel, Washington, D. C. Dr. H. Boyd Stewart, Tulsa, Okla., president of the national association, will address the group Operative clinics will be held and both scientific and technical exhibits will be on display.

Medical Library Association Meeting.—The Medical Library Association will hold its annual meeting April 10-14 with headquarters at the Hotel Galvez, Galveston, Texas. The library of the University of Texas Medical Branch will be the host. Among the speakers will be Dr. John F. Fulton, New Haven, Conn., on "Function of Historical Collections in Medical Libraries."

Mr. Baruch Honored.—In recognition of the international influence of his activities in advancing the cause of physical medicine, honorary membership in the British Association of Physical Medicine has been granted to Mr. Bernard M. Baruch, statesman and founder in 1944 of the Baruch Committee on Physical Medicine. A $1,100,000 grant established the committee, whose objectives are increasing the number of physicians trained to teach and use physical medicine, providing for more extensive basic and clinical research and insuring the proper use of physical medicine in relationship to wartime rehabilitation and peacetime preparedness.

American Medical Golfing Association.—The Seaview Country Club has been chosen for the thirty-third tournament of the American Medical Golfing Association scheduled for June 6 during the American Medical Association session in Atlantic City. Dr. Jean A. Gruhler, 1616 Pacific Avenue, Atlantic City, is chairman of the local committee on arrangements. Drs. William C. Speidel, Seattle, and Charles E. Shannon, Chicago, president and president-elect respectively of the American Medical Golfing Association, announce that the Bay Course at Seaview will be utilized by medical golfers playing only 18 holes while both the Bay Course and the Woods Course will test the ability of the 36 hole golfers. Applications for A. M. G. A. Fellowship are available by writing Secretary Bill Burns, 2020 Olds Tower, Lansing 8.

College of Surgeons Sectional Meeting.—The American College of Surgeons will hold a sectional meeting for the Middle and Southern Atlantic states March 15-16 at the Hotel Statler in Washington, D. C. Following the dinner meeting March 15 at which Dr. Jaul B. Magnuson, Washington, D. C., will preside, a symposium on cancer will be held for the medical group. The speakers will be Drs. Henry W. Cave, New York; William E. Adams, Chicago, and Grantley W. Taylor, Boston. The hospital group will hold a meeting at 8 p. m. on "Hospital and Medical Public Relations" with Dr. Edwin L. Crosby of Baltimore presiding. Presiding officers at the two luncheon meetings for the medical group will be Rear Admiral Morton D. Willcutts, M.C., Bethesda, Commanding Officer, National Naval Medical Center, and Major General Raymond W. Bliss, M.D., Washington, Surgeon General, U. S. Army.

Gordon Research Conferences.—The Gordon Research Conferences for 1949, sponsored by the American Association for the Advancement of Science and formerly known as the Gibson Island Research Conferences, will be held June 20-September 2 at Colby Junior College, New London, N. H. The Gordon Research Conferences were established to stimulate research in universities, research foundations and industrial laboratories. This purpose is achieved by an informal type of meeting. The afternoons are available for recreation, reading, resting or participation in discussion groups. The purpose of the program is primarily to bring experts up to date on the latest developments and to provoke suggestions as to underlying theories and profitable methods of approach for making further progress. All information presented is not to be used without specific authorization of the person making the contribution, and no publications are prepared as emanating from the conferences. Persons interested in attending the conferences are requested to send in their applications on or before April 1 to the director, W. George Parks, Department of Chemistry, Rhode Island State College, Kingston, R. I. Each applicant must state the institution or company with which he is connected and the type of work in which he is most interested. Attendance at each conference is limited to 100.

American College of Physicians.—The annual session of the American College of Physicians will be held March 29-April 1 with headquarters at the Waldorf-Astoria Hotel, New York. Qualified physicians who are nonmembers are invited to attend but will be charged a registration fee of $15. Members of the Medical Corps of the Army and Navy, the U. S. Public Health Service and Veterans Administration, either of the United States or of Canada, may attend on presentation of credentials. Those speaking by invitation at the general sessions include:

Stanhope Bayne-Jones, New York, The Hospital as a Center of Preventive Medicine.
J. Earle Moore, Baltimore, Treatment of Syphilis.
J. Lawrence Pool, New York, Prefrontal Operations for the Treatment of Mental Illnesses.
Charles T. Dotter, New York, Clinical Angiocardiography.
George F. Cahill, New York, Diagnosis and Treatment of Pheochromocytoma.
Chris J. D. Zarafonetis, Ann Arbor, Mich., Therapeutic Possibilities of Para-Aminobenzoic Acid.
Stuart Mudd, Philadelphia, Electron Microscopy in Relation to the Medical Sciences.
Theodore E. Woodward, Baltimore, Chloromycetin and Aureomycin: Therapeutic Results.
Harry M. Rose, New York, Clinical Features and Laboratory Diagnosis of Rickettsial Pox.
DeWitt Stetten Jr., New York, Use of Isotopes as Metabolic Tracers.
Allen O. Whipple, New York, Surgery of Malignant Tumors of the Ampullary Area and Pancreas.
Robert R. Linton, Boston, Treatment of Bleeding Esophageal Varices by Portacaval Shunts.
Shields Warren, Boston, and John Z. Bowers, Washington, D. C., Acute Radiation Syndrome in Man.
Homer F. Swift, New York, Etiology of Rheumatic Fever.

The John Phillips Memorial Lecture will be given by Dr. Edwin B. Astwood, Boston, on "Natural Occurrence of Antithyroid Compounds as a Cause of Simple Goiter." Those speaking by invitation at the morning lectures offered on Wednesday and Friday include:

Homer W. Smith, Sc.D., New York, Clinical Implications of Recent Studies of Renal Function.
George N. Papanicolaou, New York, Survey of the Actualities and Potentialities of Exfoliative Cytology in Cancer Diagnosis.
John R. Neefe, Philadelphia, Viral Hepatitis: Problems and Progress.
John S. L. Browne, Montreal, Canada, Response of the Adrenal Cortex to Disease and Injury.

Clinics and clinical pathologic conferences will be conducted on Tuesday and Thursday mornings. At the annual convocation Wednesday evening at 8:30 Dr. Walter W. Palmer, New York, president of the college, will speak on "The Internist, Past, Present and Future," and the Convocation Oration will be presented by Henry A. Moe, a New York lawyer, on "The Doctor as Citizen." The banquet speaker Thursday evening will be David E. Lilienthal, LL.D., Washington, D. C.

CORRECTION

Research Grant from Lakeside Laboratories.—In the article entitled "Use and Misuse of Endocrine Therapy in Sterility," by Dr. Edward T. Tyler in The Journal, February 26, page 560, the first footnote in small type at the bottom of the page is in error and should have stated that certain studies in connection with this report were aided by a research grant from Lakeside Laboratories, Inc., Milwaukee.

Dosage of Undecylenic Acid.—In the article by Henry Harris Perlman in The Journal, February 12, entitled "Undecylenic Acid in Psoriasis and Neurodermatitis," page 446 under "Dosage, Method of Administering Undecylenic Acid, Untoward Effects and Reactions," line 5 should read as follows: "The initial dose for most adults is now 5 perles, each containing 0.5 Gm. of undecylenic acid, given three times daily after or before meals or in divided doses, with a daily total of 7.5 Gm." The tenth line should read as follows: "The effective dose for the average adult patient seems to be 15 or 20 perles (10 Gm.), given daily in divided doses for many weeks, without any harmful effect and without any disturbances of the gastrointestinal tract."

Marriages

William H. Victor, Rockaway Beach, N. Y., to Miss Priscilla Slesinger of Hewlett, N. Y., December 26.

James Clinton Prose, Memphis, Tenn., to Miss Ina Grace Ryan of Greensboro, N. C., at Grenada, Miss., December 17.

R. Kirby West, Oakland, Calif., to Miss Ann Kuchmy of Rochester, N. Y., December 27.

William Thomas Bacon, London, Ohio, to Miss Jean Marilyn Hackett of South Charleston, December 29.

Louis Gordon Sinclair to Miss Martha Elizabeth Niven, both of Raleigh, N. C., December 10.

Gardner Middlebrook, New York, to Miss Jane Machia of Water Valley, Texas, November 26.

George W. Weber, Reading, Pa., to Miss Harrie Louise Beckey of Harrisburg, December 17.

Deaths

Harry Stack Sullivan, Washington, D. C.; born in Norwich, N. Y., Feb. 21, 1892; Chicago College of Medicine and Surgery, 1917; member of the American Psychoanalytic Association, American Psychiatric Association, of which he had been secretary, and the American Orthopsychiatric Association; from 1923 to 1930 associate professor of psychiatry at the University of Maryland School of Medicine in Baltimore; served as director of clinical research at the Sheppard and Enoch Pratt Hospital in Towson, Md.; formerly professor of psychiatry and director of the department of psychiatry and neurology at the Georgetown University School of Medicine; faculty chairman of the Washington School of Psychiatry and president of the William Alanson White Psychiatric Foundation; during World War II consultant on psychiatry for the Selective Service System; received the first William Alanson White Memorial Award for distinguished contributions to psychiatry; editor of *Psychiatry;* died in Paris, France, January 14, aged 56, of cerebral hemorrhage.

Charles Edward Kiely ⊕ Cincinnati; born in Cincinnati June 22, 1887; Ohio-Miami Medical College of the University of Cincinnati, 1913; assistant professor of psychiatry at his alma mater; member of the House of Delegates of the American Medical Association from 1930 to 1932 and from 1934 to 1941; past president of the Cincinnati Academy of Medicine; member of the American Psychiatric Association and the Central Neuropsychiatric Association; on the staff of Christ Hospital, where he died December 30, aged 61, of carcinoma of the esophagus and tongue.

Arial Wellington George ⊕ Boston; Tufts College Medical School, Boston, 1906; specialist certified by the American Board of Radiology, Inc.; formerly on the faculty of his alma mater; member of the American Roentgen Ray Society, New England Roentgen Ray Society and the Radiological Society of North America; co-author of several books; affiliated with the Glover Memorial Hospital in Needham, Cape Cod Hospital, Hyannis, Lynn (Mass.) Hospital and the Brooks Hospital in Brookline, where he died December 24, aged 66, of coronary disease.

John Joseph Allen, Bell, Calif.; Baltimore Medical College, 1901; died December 6, aged 74, of lung abscesses and arteriosclerosis.

Victor Ludwig Altmann, New York; Medizinische Fakultät der Universität, Wien, Austria, 1905; member of the American Medical Association; died recently, aged 68, of coronary thrombosis.

Maurice P. Apmadoc, Chicago; Harvey Medical College, Chicago, 1902; also a dentist; died in the Cook County Hospital recently aged 76, of arteriosclerosis and myocarditis.

Florence Bailey, Lawrence, Mass.; College of Physicians and Surgeons, Boston, 1903; member of the American Medical Association; died December 24, aged 71, of chronic myocarditis and cerebral hemorrhage.

Francis Senter Bascom ⊕ Oakland, Calif.; Harvard Medical School, Boston, 1929; specialist certified by the American Board of Internal Medicine; on the staff of the Peralta Hospital; died December 23, aged 46.

Albert Raymond Bell, Tomah, Wis.; Wisconsin College of Physicians and Surgeons, Milwaukee, 1900; member of the American Medical Association; past president of the school board, of which he had been a member for many years; affiliated with St. Mary's Hospital in Sparta, where he died December 12, aged 76, of cerebral hemorrhage.

George A. Bradford, Columbia, Mo.; St. Louis College of Physicians and Surgeons, 1888; on the staffs of the Boone County and Noyes hospitals; died November 15, aged 83.

Clarence Hughes Bulkley ⊕ La Plata, Mo.; Keokuk (Ia.) Medical College, College of Physicians and Surgeons, 1907; served during World War I; died November 8, aged 65.

John Kendall Chorlog ⊕ Madison, Wis.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1907; died December 14, aged 75, of coronary thrombosis.

Irving Taylor Clark, Rochester, N. Y.; University of Pennsylvania Department of Medicine, Philadelphia, 1902; died December 19, aged 70, of cerebral hemorrhage.

George C. Collins, Wheatcroft, Ky.; Hospital College of Medicine, Louisville, 1907; died December 14, aged 71.

Isaac Cohn, Brooklyn; University and Bellevue Hospital Medical College, New York, 1914; member of the American Medical Association; affiliated with Beth Moses Hospital and the Brooklyn Cancer Institute; died December 9, aged 61.

Emery Golden Coyle, Coffeyville, Kan.; St. Louis University School of Medicine, 1911; member of the American Medical Association; died in the Research Hospital, Kansas City, Mo., December 11, aged 59, of duodenal ulcer and cerebral hemorrhage.

Wilbur Saunders Crowell, Brecksville, Ohio; Western Reserve University Medical Department, Cleveland, 1899; veteran of the Spanish-American War; formerly member of the city council; served on the staff of Cleveland City Hospital; died December 9, aged 76, of cerebral hemorrhage.

Leo Francis Crowley, Jersey City, N. J.; Georgetown University School of Medicine, Washington, D. C., 1909; medical examiner for the police and fire departments; affiliated with St. Francis and Christ hospitals; died December 9, aged 64.

Carl Albert Dahlen ⊕ Boston; Tufts College Medical School, Boston, 1918; instructor in dermatology at the Boston University School of Medicine; on the staff of the Massachusetts Memorial Hospitals, where he died recently, aged 56, of cerebral hemorrhage.

Paul Charles Dier, Milwaukee; Marquette University School of Medicine, Milwaukee, 1915; member of the American Medical Association; died December 18, aged 61, of coronary occlusion.

Frank Lumsden Eastman, Kingston, N. Y.; New York Homeopathic Medical College and Flower Hospital, New York, 1909; member of the American Medical Association; on the staff of the Benedictine Hospital; died in Middletown, December 11, aged 62.

Harry George Erwin, Lagrange, Ind.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1909; member of the American Medical Association; served during World War I; formerly health commissioner of Lagrange County; served as coroner of Allen County; on the staff of Lagrange County Hospital; died November 25, aged 65, of carcinoma of the gallbladder and liver.

Joseph Harold Evans, New Haven, Conn.; Boston University School of Medicine, 1902; formerly secretary of the Connecticut Homeopathic Medical Examining Board; died November 25, aged 70, of coronary occlusion.

Albert Fisher, North Judson, Ind.; Central College of Physicians and Surgeons, Indianapolis, 1904; member of the American Medical Association; county health officer; affiliated with the Holy Family Hospital in La Porte; head of the Selective Service Board of Starke County during World War II; died December 3, aged 70, of cardiac decompensation and lymphosarcoma.

Louis P. G. Gouley ⊕ Huntington, N. Y.; Denver and Gross College of Medicine, 1908; since 1916 on the attending staff of the Huntington Hospital, where he was chief of obstetrics from 1933 to 1938; died December 12, aged 70, of cerebral thrombosis.

William Charles Gulde, St. Cloud, Minn.; Drake University College of Medicine, Des Moines, 1907; died suddenly, recently, aged 67.

Charles O. Hadley, Nashville, Tenn.; Meharry Medical College, Nashville, Tenn., 1899; formerly on the faculty of his alma mater; served in France during World War I; affiliated with the George W. Hubbard Hospital of Meharry Medical College; died in the Veterans Administration Hospital December 14, aged 72, of diabetes mellitus.

Ira May Hardy, Kinston, N. C.; Medical College of Virginia, Richmond, 1901; member of the American Medical Association; past president of the Lenoir County Medical Society and the Seaboard Medical Association; formerly affiliated with the Caswell Training School; one of the founders of the Fowle Memorial Hospital in Washington; for many years a trustee of the Good Shepherd Hospital at New Bern; died November 21, aged 74.

Carlos Louis Henriquez, New York; Columbia University College of Physicians and Surgeons, New York, 1900; died in South America, recently, aged 69, of carcinoma of the rectum.

Alexander Codling Howe, Brooklyn; University of the City of New York Medical Department, New York, 1893; member of the American Medical Association; fellow of the American College of Surgeons; specialist certified by the American Board of Otolaryngology; affiliated with the Brooklyn Eye and Ear Hospital and the Jewish Hospital; died December 23, aged 85, of chronic myocarditis.

Chiles Lester Keithly, Milo, Mo.; Washington University School of Medicine, St. Louis, 1904; died in Nevada November 12, aged 75, of heart disease.

John Henry Kelley, Atlanta, Ga.; Atlanta College of Physicians and Surgeons, 1905; died November 20, aged 85, of chronic endocarditis and arteriosclerosis.

George Edwin Knappenberger, Kansas City, Mo.; University of Kansas School of Medicine, Kansas City, Kan., 1911; member of the American Medical Association; formerly member of the Missouri State Board of Health; served during World War I; affiliated with St. Luke's, St. Joseph's and the Research hospitals; died in San Diego, Calif., December 27, aged 60, of coronary thrombosis.

Alexander Marcellus Lisenbee, Sparkman, Ark.; Tulane University of Louisiana School of Medicine, New Orleans, 1910; member of the American Medical Association; died in Baptist Hospital, Litle Rock, November 11, aged 62, of heart disease.

Aljah Wright Lloyd, Hammond, Ind.; Hospital College of Medicine, Louisville, Ky., 1900; member of the American Academy of Ophthalmology and Otolaryngology; died in St. Margaret Hospital November 19, aged 78, of coronary thrombosis.

William Kiddoo Lloyd ⊕ Anniston, Ala.; Tulane University of Louisiana School of Medicine, New Orleans, 1921; specialist certified by the American Board of Obstetrics and Gynecology, Inc.; served during World War I; past president of the Calhoun County Medical Society and the Alabama Association of Obstetricians and Gynecologists; chief of rotating staff in obstetrics at the Anniston Memorial Hospital; instantly killed December 23, aged 49, in a plane crash.

Charles Carey Maupin ⊕ Louisville, Ky.; University of Louisville School of Medicine, 1912; affiliated with St. Joseph's Infirmary, Kentucky Baptist Hospital, Norton Memorial Infirmary, Methodist Deaconess Hospital, SS. Mary and Elizabeth Hospital, and the Children's Free Hospital; died in Buechel December 5, aged 60, of carcinoma of the pancreas.

John Henry Morris, Pulaski, Tenn.; University of Louisville (Ky.) Medical Department, 1909; member of the American Medical Association; served in France during World War I; county health officer; died November 26, aged 61, of carcinoma of the stomach.

Jonah Nichols, Gulfport, Miss.; University of Virginia Department of Medicine, Charlottesville, 1887; member of the American Medical Association; died in Memorial Hospital December 26, aged 83, of heart disease.

Harold Frederick Noble ⊕ Fort Madison, Iowa; State University of Iowa College of Medicine, Iowa City, 1926; city health commissioner; died December 28, aged 46, of cerebral hemorrhage.

John Aldine Norford, Lynchburg, Va.; University of Virginia Department of Medicine, Charlottesville, 1903; drowned near Gladstone December 16, aged 72, when his boat capsized while he was duck hunting.

William Burrill Odenatt ⊕ Philadelphia; Medico-Chirurgical College of Philadelphia, 1897; secretary of the local draft board no. 52 during World War II; since 1942 medical director of the Stetson Hat Company; formerly on the staffs of Stetson and Nazareth hospitals; died December 3, aged 62.

Paul Julius Opperman, Cleveland; University of Wooster Medical Department, Cleveland, 1895; died in St. Luke's Hospital December 17, aged 76, of cerebral hemorrhage.

Marion Ousley-Russell, Elgin, Ill.; the Hahnemann Medical College and Hospital, Chicago, 1890; died December 7, aged 89, of cerebral hemorrhage and arteriosclerotic heart disease.

Harry S. Piggins, Milwaukee; Rush Medical College, Chicago, 1885; founder and a director of the Wisconsin State Bank, of which he was vice president; died December 20, aged 88, of cardiovascular disease.

Florence Faulkner Poole, Norco, Calif.; College of Physicians and Surgeons, Boston, 1904; died in the Corona (Calif.) Hospital recently, aged 69, of cerebral hemorrhage.

Frank Julius Quist ⊕ Worcester, Mass.; Rush Medical College, Chicago, 1905; an officer during World War I; director and vice president of the Guaranty Trust Company; served on the staffs of the Fairlawn and City hospitals; died in St. Petersburg, Fla., December 20, aged 74, of leukemia.

William Egbert Ragsdale ⊕ Memphis, Tenn.; College of Physicians and Surgeons, Memphis, 1908; for many years on the staff of St. Joseph's Hospital; served as local surgeon for the Illinois Central Railroad; died December 8, aged 67, of coronary thrombosis.

James Emery Rawlings ⊕ Daytona Beach, Fla.; University of Maryland School of Medicine, Baltimore, 1904; veteran of the Spanish-American War and World War I; died in Halifax Hospital December 23, aged 69.

Ezra Clark Rich, Los Angeles; Jefferson Medical College of Philadelphia, 1894; member of the American Medical Association and the Utah State Medical Association; fellow of the American College of Surgeons; formerly practiced in Ogden, Utah, where he was on the staff of the Thomas D. Dee Memorial Hospital; died in the Good Samaritan Hospital December 27, aged 84, of cerebral thrombosis.

Luther Enoch Roberts, Rosedale, W. Va.; University of Louisville (Ky.) Medical Department, 1907; died December 15, aged 74, of heart disease.

Richard Ambrose Roche, Chicago; Northwestern University Medical School, Chicago, 1912; formerly on the staff of Holy Cross Hospital; affiliated with the Little Company of Mary Hospital, where he died December 26, aged 61, of heart disease.

Stephen T. Ross, Winder, Ga.; Louisville (Ky.) Medical College, 1891; member of the American Medical Association; died in St. Mary's Hospital, Athens, December 28, aged 81, of bronchopneumonia and carcinoma of the stomach.

Claude Nelson Rucker, Marytown, W. Va.; Medical College of Virginia, Richmond, 1903; served during World War I; formerly associated with the Veterans Administration in Charleston; died November 29, aged 68, of cerebral hemorrhage.

William Morvel Wesley Rynard ⊕ Stamford, Conn.; University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1924; member of the American Society of Anesthetists, Inc.; died December 23, aged 49.

Charles Gilbert Sabin, Portland, Ore.; Northwestern University Medical School, Chicago, 1907; died in Herrin, Ill., December 11, aged 72, of injuries received in an automobile accident.

Hans Richard Sauer ⊕ Buffalo; Friedrich-Wilhelms-Universität Medizinische Fakultät, Berlin, Prussia, 1929; specialist certified by the American Board of Urology, Inc.; died in Roswell Park Memorial Institute November 30, aged 45, of heart disease.

Stephen Douglass Sauer, Harrisburg, Pa.; Jefferson Medical College of Philadelphia, 1891; Minneapolis College of Physicians and Surgeons, 1896; died in Harrisburg State Hospital recently, aged 87, of bronchopneumonia.

Louis John Saxe ⊕ Phoenix, Ariz.; Duke University School of Medicine, Durham, N. C., 1934; certified by the National Board of Medical Examiners; specialist certified by the American Board of Psychiatry and Neurology, Inc.; member of the American Psychiatric Association; formerly superintendent of the Arizona State Hospital at Phoenix; died in St. Joseph's Hospital December 13, aged 40, of cardiac decompensation.

Franklin E. Schenck, Burlingame, Kan.; College of Physicians and Surgeons, Keokuk, Iowa, 1882; member of the American Medical Association; died November 19, aged 92, of carcinoma of the descending colon and chronic prostatitis.

Edwin Schiller ⊕ Elizabeth, N. J.; Friedrich-Wilhelms-Universität Medizinische Fakultät, Berlin, Prussia, Germany, 1919; affiliated with the Beth Israel and St. Michael's hospitals in Newark; died November 18, aged 57, of coronary thrombosis

Jerome Gerald Schnedorf, Santa Barbara, Calif.; Northwestern University Medical School, Chicago, 1938; specialist certified by the American Board of Surgery; served during World War II; member of the American Medical Association, which in 1940 awarded him the Certificate of Merit for his research on anoxia; died at Big Bear, in December, aged 35, of anoxia caused by a gas heater.

Francis Marion Burlingame Schramm, Johnstown, Pa.; Jefferson Medical College of Philadelphia, 1909; served during World Wars I and II; formerly member of the school board; died in Venice, Fla., November 15, aged 65.

Solomon Schwager ⊕ Pittsfield, Mass.; University and Bellevue Hospital Medical College, New York, 1917; affiliated with St. Luke's Hospital and the House of Mercy Hospital, where he died November 30, aged 58, of hypertensive cardiovascular disease.

Clarence William Schwalm ⊕ Shoemakersville, Pa.; Temple University School of Medicine, Philadelphia, 1923; died November 2, aged 64, of coronary occlusion.

Otis Elmer Senour, Erlanger, Ky.; Hospital College of Medicine, Louisville, 1904; died November 5, aged 67.

Glenn Elmo Shawhan, Nampa, Idaho; Denver and Gross College of Medicine, 1904; member of the American Medical Association, American Academy of Ophthalmology and Otolaryngology and the Pacific Coast Oto-Ophthalmological Society; died recently, aged 72.

Joseph Peter Sheridan ⊕ Laurelton, N. Y.; University of the City of New York Medical Department, New York, 1892; an Affiliate Fellow of the American Medical Association; formerly chief diagnostician for the health department in Queens County; for many years on the staff of St. John's Hospital in Brooklyn; at one time affiliated with the Colored Home and Hospital in Manhattan and the Home for the Blind at Richmond Hill; died November 13, aged 78.

Andrew George Shetter, Richmond, Va.; Medical College of Virginia, Richmond, 1917; member of the American Medical Association; died December 13, aged 61, of cerebral hemorrhage and hypertension.

Joseph K. Shriver Jr., Cambridge, Md.; Baltimore Medical College, 1892; member of the American Medical Association; died November 12, aged 71, of coronary occlusion and hypertension.

Walter Heinman Simmons ⊕ Pine Bluff, Ark.; Vanderbilt University School of Medicine, Nashville, Tenn., 1903; died December 14, aged 69, of coronary occlusion.

Benjamin James Slater ⊕ Rochester, N. Y.; Cornell University Medical College, New York, 1914; member of the American Association of Industrial Physicians and Surgeons; served during World War I; associate medical director of Eastman Kodak Company; affiliated with Rochester General and Strong Memorial hospitals; died December 4, aged 60, of coronary occlusion.

Leith Hollingshead Slocumb, Los Angeles; Washington University School of Medicine, St. Louis, 1913; member of the American Medical Association; died November 22, aged 63, of coronary occlusion.

George Lee Smith, Morrison, Va.; College of Physicians and Surgeons, Baltimore, 1892; member of the American Medical Association; died November 22, aged 79.

James Atkinson Smith, St. Louis; Barnes Medical College, St. Louis, 1905; for many years affiliated with the city health department; examining physician for the city board of education; died in Christian Hospital December 30, aged 67, of pneumonia.

Lester Pennington Smith, Muskogee, Okla.; University of Oklahoma School of Medicine, Oklahoma City, 1925; member of the American Medical Association; chief medical officer for the regional office of the Veterans Administration; died in Veterans Administration Hospital, Jefferson Barracks, Mo., recently, aged 48.

Ralph Vernon Smith, Britton, Okla.; Missouri Medical College, St. Louis, 1898; member of the American Medical Association; fellow of the American College of Surgeons; past president of the Oklahoma State Medical Association and the Oklahoma County Medical Society; served during World War I; died November 27, aged 77.

William Hallick Snyder, Brooklyn; Long Island College Hospital, Brooklyn, 1888; served as senior surgeon and member of the board of directors of the Brooklyn Eye and Ear Hospital; member of the staffs of St. Christopher's Hospital, Holy Family Hospital, St. Catherine's Hospital and St. John's Hospital; died November 12, aged 86, of cerebral hemorrhage.

Jean David Spaid ⊕ Dayton, Ohio; Ohio State University College of Medicine, Columbus, 1922; specialist certified by the American Board of Anesthesiology; member of the American Society of Anesthetists; on the staffs of the Good Samaritan and Miami Valley hospitals; consulting anesthetist for the Ohio Masonic Home in Springfield; died December 14, aged 54, of heart disease.

John M. Spaulding ⊕ Los Angeles; University of Louisville (Ky.) Medical Department, 1907; medical examiner for many insurance companies; medical director for the Unity Mutual Life Insurance Company; died in the San Pedro (Calif.) Hospital, November 13, aged 67, of cerebral thrombosis.

R. P. Ellis Starr ⊕ Denver; University of Louisville (Ky.) Medical Department, 1912; died in the Colorado General Hospital November 10, aged 66.

Joseph Mefford Steim, New Kensington, Pa.; Medico-Chirurgical College of Philadelphia, 1898; member of the American Medical Association and the American Academy of Ophthalmology and Otolaryngology; vice president and director of the First National Bank; consultant in ophthalmology at the Citizens General Hospital, where he died November 13, aged 71, of carcinoma of the pharynx.

Thomas Calderwood Stephens, Sioux City, Iowa; College of Physicians and Surgeons, Medical Department Kansas City University, 1904; died November 24, aged 72.

Daniel Cornelius Sullivan, Jersey City, N. J.; McGill University Faculty of Medicine, Montreal, Canada, 1919; affiliated with the Berthold S. Pollak Hospital for Chest Diseases; assistant medical director of the Central Railroad of New Jersey; died in Christ Hospital December 20, aged 55, of primary carcinoma of the liver.

Clyde Byron Terwillegar, Steubenville, Ohio; University of Cincinnati College of Medicine, 1912; past president of the Jefferson County Medical Society; died recently, aged 58.

Henry Keener Tippins, Geneva, Ala.; Chicago College of Medicine and Surgery, 1908; member of the American Medical Association; died in Hartford November 3, aged 67, of a spinal injury due to an automobile accident in 1945.

William Darracott Travis ⊕ Covington, Ga.; Baltimore Medical College, 1893; served as health officer of Newton County and Covington; killed instantly December 6, aged 78, in an automobile accident.

Raymond Leo Traynor ⊕ Omaha; John A. Creighton Medical College, Omaha, 1919; clinical professor of medicine at his alma mater; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; affiliated with Creighton Memorial St. Joseph's Hospital; died November 10, aged 54, of malignant hypertension and basilar cerebral hemorrhage.

Homer A. Trotter, Buffalo; University of Buffalo School of Medicine, 1915; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; affiliated with the Buffalo General Hospital and the U. S. Marine Hospital; died October 19, aged 63, of aortic stenosis and rheumatic fever.

Edward Logan Underwood, Oklahoma City; Barnes Medical College, St. Louis, 1906; died December 11, aged 79.

Henry Anthony Viti, Jersey City, N. J.; Regia Università degli Studi di Roma, Facoltà di Medicina e Chirurgia, Italy, 1936; member of the American Medical Association; served during World War II; on the staff of St. Francis Hospital, where he died December 11, aged 41, of carcinoma of the right bronchus.

Alphonse Edmund Walch ⊕ Minneapolis; St. Louis University School of Medicine, 1933; on the faculty of the University of Minnesota Medical School; specialist certified by the American Board of Internal Medicine; affiliated with the Minneapolis General Hospital, Abbott Hospital and St. Mary's Hospital, where he died November 14, aged 41, of carcinoma of the lung.

Frank Jerome Walker, Wichita, Kans.; Kansas Medical College, Medical Department of Washburn College, Topeka, 1902; served in France during World War I; at one time member of the county medical board; died in St. Francis Hospital December 1, aged 74, of cerebral hemorrhage.

James York Welborn ⊕ Evansville, Ind.; Marion-Sims College of Medicine, St. Louis, 1899; fellow of the American College of Surgeons; affiliated with Welborn Memorial Baptist Hospital, where he died December 21, aged 75, of carcinoma of the pancreas.

Frank Raymond Whelply Jr., Long Beach, Calif.; University of Buffalo School of Medicine, 1918; member of the American Medical Association; served during World War I; for many years chief of the division of communicable diseases of the Buffalo Department of Health; on the staffs of Seaside and Community hospitals; died November 24, aged 55, of coronary disease.

John Edwin Wilson, Falmouth, Ky.; Medical College of Ohio, Cincinnati, 1888; member of the American Medical Association; for many years mayor; died December 27, aged 81, of coronary occlusion.

Charles Joseph Wivell, Scranton, Pa.; Baltimore Medical College, 1901; died in the Moses Taylor Hospital November 26, aged 72, of coronary thrombosis.

George W. Wood, Oxford, Fla.; Birmingham Medical College, 1905; died November 2, aged 85.

Feb. 3, 1949.

Epidemic of Salmonella Gastroenteritis

During 1948 in Brisbane, Queensland, an epidemic of gastroenteritis affected over 500 children with 89 deaths. The epidemic was due to Salmonella bovis-morbificans. The infection was concentrated in infants under 2 years old. Of 150 persons from whom the organisms were isolated, 108 were infants under 1 year and 30 were between 1 and 2 years of age. The outstanding clinical feature was a degree of toxemia out of all proportion to the symptoms referable to the bowel. There was little mucus and blood, the stools were fluid or semifluid and soon became solid or pasty. It was in this latter stage that the causative organism was more readily isolated from the stool. The children remained infected for a longer period than their clinical condition would indicate.

The epidemic was predominantly institutional; 56 per cent of the proved cases occurred in hospitals or institutions which care for young children, and 11 per cent occurred in housing camps. The incidence of infection was higher at weaning stage, and lower in infants fully breast fed. There were undoubtedly a considerable number of cases of cross infection at the Brisbane Children's Hospital. The evidence indicated that the transmission was through the medium of the infected napkin, and it became necessary to institute a regimen whereby the napkins of all children, prior to any cleansing action were immersed in boiling water for twenty minutes.

The bacteriologic studies of these infections were made by I. M. and M. J. Mackerras of the Queensland Institute of Medical Research in Brisbane. These investigators received considerable help from the descriptions by Ewing and Bruner of their experience with the United States Army Laboratory in Italy, the account being published in the *American Journal of Clinical Pathology* (17: 1, 1947).

In a more detailed study of the means of transmission of infection, the Salmonella organisms were found in cockroaches, mice, rats and cats. The organisms were also isolated from brushes and sinks used in the cleansing of napkins and from nail brushes used by the nursing staff. The sulfonamide group of drugs was ineffective in the treatment of this condition. Therapy was mainly supportive to overcome the dehydration and malnutrition. Intravenous therapy with isotonic sodium chloride solution, dextrose, human serum and especially protein hydrolysate was a routine in the treatment. The best results were given by protein hydrolysate. Several cases occurred in the Women's Hospital, among the newborn babies. Mackerras considers that diagnostic cultures should be continued to not less than the sixth, and clearing cultures during convalescence to not less than the third, before a Salmonella infection is excluded.

Studies in the Transmission of Rubella

During the last decade, rubella (German measles) has changed from a trivial infection of little medical interest to an important public health problem. This is due entirely to the recognition in Australia of the fact that infection of a woman in the early months of pregnancy was liable to be followed, in a high percentage of cases, by serious damage to the infant, notably cataract and nerve deafness.

A fresh prevalence of rubella in Victoria provided an opportunity for the Walter and Eliza Hall Institute of Medical Research to undertake experiments in the transmission of this infection. Professor Burnett made intensive efforts to cultivate the virus in chick embryos by various routes and at various ages, but was unsuccessful. No lesions were observed, nor were positive complement fixation reactions obtained with human convalescent serum. Negative complement fixation results were also obtained with concentrated throat washings as antigen.

Infection was induced in volunteer human subjects (mostly university women students) by inhalation of atomized throat washings; a compressed air atomizer was found to be the most effective. Nine infections were produced in 16 subjects, and, since none of the other 7, who were in close contact with the infected subjects, contracted rubella as secondary cases, it is felt that this dosage was fully effective with all susceptible persons.

These studies indicate that the virus is present in high concentration in washings from the throat taken at the height of the rash. The virus can be preserved in fully active state for at least three months at the temperature of solid carbon dioxide. The virus is filterable through a 800 micron membrane and is unaffected by high concentrations of penicillin. The incubation period to the appearance of the rash ranged from 13 to 20 days, with a mean of 15.9 days. The disease produced by inoculation was transmissible by ordinary contact to susceptible subjects.

The practical significance of this work is that it is now possible, by inducing infection in the young woman, to guarantee her the virtually complete elimination of the chance of infection during any subsequent pregnancy.

The second part of the study was the protective effect of convalescent serum from 55 convalescent volunteers. Serum was prepared and a concentrated gamma globulin was produced. This globulin has been used to prevent infection in women who have been exposed to rubella at a vulnerable stage of pregnancy. In 22 instances of proved or possible contact serum has been administered, and so far in none of these cases has a rubella rash subsequently been confirmed.

Social and Nutritional Factors in Disease

The study of the domestic, economic, occupational, educational and psychologic aspects of patients attending the Royal Melbourne Hospital provided valuable data as to the cause of malnutrition. Investigations were made by Miss C. N. Turner, a dietitian, and Miss M. A. Mackay, an almoner, working under the direction of the clinical research unit of the Walter and Eliza Hall Institute of Medical Research. Three important classes resolved themselves as this study developed. First is the solitary existence group, which included those who live alone in poor circumstances in a room or hostel, and who are sorely tempted to cast aside the normal Australian diet and resort to infrequent, monotonous, ill balanced, ill prepared meals.

The second group is occupational. The nature of a man's occupation may influence his dietetic habits; for example, a cook is subjected to considerable mental and physical stress and is continually sampling foods often rich in carbohydrate and deficient in protein and vitamins. These two factors dull the appetite and discourage him from taking regular meals. Truck drivers, traveling salesmen and night watchmen are others who suffer in this way.

The third is that group which takes alcohol to excess. The alcohol supplies a considerable number of calories and satisfies the appetite. The appetite is also dulled by the development of chronic gastritis. The chief deficiencies noted in this series were of calcium, iron and members of the vitamin B complex, especially thiamine hydrochloride. Minor deficiency in vitamin C was common, and 2 cases of frank scurvy were encounter

DENMARK

COPENHAGEN, Feb. 9, 1949.

Advice on Influenza

The State Serum Institute in Copenhagen has recently issued a memorandum on influenza to serve as a guide to its most outstanding features. It is pointed out that the present epidemic seems to have started last December in Italy, whence it has spread slowly to neighboring countries. In Italy and France it has been very extensive, some 20 to 25 per cent of the population contracting it. But hitherto it has always run a mild clinical course, fever lasting only two or three days and the patient being well again within a week. Pulmonary complications are exceptional and show a preference for the old and feeble. The mortality has been almost negligible. Laboratory investigations have led to the recognition of the B virus in Italy and the A virus in France, but in nearly half of the cases investigated there has been some doubt about the etiology, and it is possible that several strains of the virus of influenza may exist side by side.

Danish doctors are advised to abstain for the present from vaccinating against influenza with standard vaccines derived from virus A and B because there are still doubts as to the etiology of the present epidemic and because the disease runs such a benign course. Besides, such vaccination against influenza offers no certain guarantee against it. The State Serum Institute wishes for the present to keep intact its stores of influenza vaccine, for which there may be a real need later on. As soon as new strains are isolated, arrangements will be made for their incorporation in the vaccine, the effectiveness of which would thus be raised; this would be well if by any chance the present epidemic were to assume a more serious character. Doctors are warned against careless despatch to the institute of material for examination; a certain technical skill is needed for the collection of such material.

The Antabus® Treatment of Alcoholism

Since we are certain to hear much about the antabus® treatment of alcoholism in the next few years, it is well at once to stake out the claims which Denmark can make to pioneer work in this field. In December 1947, the firm of chemists Medicinalco gave Dr. O. Martensen-Larsen (who has for long associated himself with the treatment of alcoholic addicts) a supply of tetraethylthiuram disulfide to which the trade name of antabus® has been applied. Given by itself in doses up to 2 Gm., it usually causes no discomfort, but when even a small quantity of alcohol is consumed at the same time, the two drugs combine to form acetaldehyde, which provokes exceedingly unpleasant reactions such as nausea and vomiting. After this condition has lasted from half an hour to four hours, the patient feels tired and drowsy, but he recovers completely in a short time. The distaste he thus acquires for alcohol may last for several days.

Dr. Martensen-Larsen has given antabus® to some 300 alcoholic addicts. Last fall he published in the Danish medical press a detailed account of his first 50 cases with an observation period of over six months. The drug was given daily, and there were no untoward complications. Social recovery or considerable improvement could be claimed in 35 cases. All the remaining 15 patients had discontinued the treatment for some reason or other. The conclusion is drawn that antabus® is effective in checking the consumption of alcohol but needs the support of intensive psychotherapy. The lay press has been quick to appreciate the dramatic element in this short cut to the alleged cure of a very chronic condition, and there are rumors of a stag party whose festivity was much impaired by the introduction of antabus® by stealth into their repast by a lady anxious to save her husband from alcoholic indiscretions. It has already been seriously suggested that chronic alcoholic addicts who have repeatedly fallen foul of the law should be given the choice between antabus® and prison.

Progress in the Radiologic Treatment of Cancer

The report for the period 1947-1948 of the Danish National Association for Combating Cancer contains much encouraging information. Nearly all the cases of cancer of the cervix of the uterus are now concentrated at the radium station for radium-roentgen treatment, and an analysis of some 4,000 patients over a five year period shows that when all the stages of this condition are included in one a cure may be claimed in approximately every other case. Since the introduction in 1940 of the roentgen-rotation treatment of cancer of the esophagus, some 500 patients have been treated for this condition at the radium station. Though a few have achieved what seems to be a permanent recovery, the effects of this treatment must be regarded as palliative rather than as permanently curative.

An analysis of 115 cases of cancer of the larynx in which radiologic treatment was given in the period from 1931 to 1942 at the radium station shows that 54 persons were cured as judged by freedom from symptoms for at least five years. In the two earliest stages of cancer of the vocal cords, roentgen treatment yielded very good results in 92 and 85 per cent respectively. Even in cases of advanced and inoperable disease, good results were achieved in 26 per cent. The report also gives an encouraging account of the radiologic treatment of 111 cases of tumors of the testicles, 40 per cent of the patients being symptom free after an interval of at least five years. The association has hitherto struggled along on a more or less voluntary basis, but recently the state has made a substantial contribution to its funds. With such material aid from public funds, the association would be more at liberty to expand its activities in certain directions such as research.

Denmark as a Center for Tuberculosis Research

It is gratifying that the Scandinavian countries in general, and Denmark in particular, are becoming more and more a tuberculosis Mecca to which doctors come from all parts of the world for inspiration and guidance. This claim depends to a large extent, but by no means exclusively, on BCG research. In the information service for February 1 of the League of Red Cross Societies it is pointed out that, under the auspices of the Danish Red Cross, forty-one doctors from eleven different countries were invited in 1948 to participate in its three month course. In an editorial note in the *Journal of the Danish Red Cross* (1949, no. 1), reference is made to the close association of the Scandinavian countries with the World Health Organization. The "Medical College" of the Danish Red Cross has provided for the free residence and postgraduate training in tuberculosis work of hundreds of doctors from all parts of the world.

An International Appointment for Dr. Gunnar Alsted

Dr. Gunnar Alsted of the University of Copenhagen, who has held a research fellowship in medicine granted by Harvard University and a senior appointment at the Bispebjerg and Fredriksberg hospitals in Copenhagen, has been appointed as from the beginning of 1949 as the Director of the Health Bureau of the League of Red Cross Societies with headquarters in Geneva.

Correspondence

LITHIUM INTOXICATION

To the Editor:—I have recently observed that one of the table salt substitutes (westsal®, marketed by Westwood Pharmaceuticals, Division of Foster-Milburn Co., Buffalo, N. Y.) may cause toxic symptoms in patients following a 200 mg. low sodium diet. This salt substitute contains 25.00 per cent lithium chloride, 0.20 per cent citric acid and 0.01 per cent potassium iodide. I feel that it is important to bring this observation to the attention of the practitioner because these symptoms may simulate those which are already present or may occur, because of the very disease for which the low sodium diet is being given. The 2 patients whom I am reporting in some detail (*Univ. Hosp. Bull.*, Ann Arbor 15: 9-10 [Feb.] 1949), after taking westsal® a few months, showed jerky tremor of the arms, unsteadiness in gait, generalized weakness, exhaustion and blurred vision. These symptoms were entirely new to the patients and disappeared a few days after withdrawal of the westsal,® no other changes having been made in their treatment. The two other patients mentioned in the report complained of a jerky tremor and generalized weakness while taking westsal.® These symptoms disappeared after withdrawal of the salt substitute and have not recurred.

After having looked up some of the old medical literature on lithium, I felt that these symptoms were rather typical of lithium intoxication. There is practically nothing being written on this subject at the present time, even in pharmacology textbooks, because lithium salts were rarely used in the present day treatment of disease until westsal® appeared on the market as a table salt substitute. Therefore, these symptoms could easily be misinterpreted and their true cause go unrecognized.

Whether or not this intoxication in my patients was due to their being on a low sodium diet, or due to their individual susceptibility to the drug or due to renal disease, I do not know. However, one of them had a normal nonprotein blood nitrogen level at the time the symptoms were rather pronounced, and routine urinalyses had always been normal. The other patient was 81 years old and may well have had some renal impairment, although a single urine specimen showed no albumin or sugar and had a specific gravity of 1.027.

Although westsal® comes closer to the taste of sodium chloride than other substitutes I have tried and although many patients can use it without toxic manifestations, I still feel that the practitioner should be warned of its possible toxic reactions, so that he may be on the lookout for them.

A. M. Waldron, M.D.,
Ann Arbor, Mich.

VITAMIN E IN HEART DISEASE

To the Editor:—The recent editorial comment concerning vitamin E in The Journal (138: 1159 [Dec. 18] 1948) seems to us to warrant discussion. In the past year, there has been extensive publicity in the lay press advocating the use of vitamin E in various forms of heart disease. Enthusiastic recommendations in such periodicals as *Coronet*, the *New York Times* and other newspapers, and extensive advertising campaigns by less scrupulous drug companies, have made the public and even some physicians all too conscious of the supposed miracles to be expected from vitamin E. Hardly a week goes by now that some one does not attempt to acquaint us with the newer therapeutics. As far as we know, there has been no published confirmation of the work emanating from Canada. A critical analysis of the glowing reports published by Vogelsang, Shute and Shute certainly did not leave us with the same degree of enthusiasm. The first editorial comment in The Journal (131: 764 [June 29] 1946) pointed out the lack of scientific basis for recommending the use of vitamin E in heart disease. In the most recent editorial discussion, however, The Journal made no mention of a number of controlled studies published in the past year, testifying to the poor results obtained with vitamin E therapy.

Makinson and colleagues (*Lancet* 1: 102 [Jan. 17] 1948) reported no improvement in 22 patients with angina pectoris treated with vitamin E. Levy and Boas (*Ann. Int. Med.* 28: 1117-1124 [June] 1948) saw no improvement with very large doses of vitamin E in 13 patients suffering from angina pectoris or cardiac failure. Baer, Heine and Gelfond (*Am. J. M. Sc.* 215: 542-547 [May] 1948) failed to note improvement in 22 patients suffering from angina pectoris, cardiac failure or hypertensive heart disease. These patients were given 400 to 600 mg. of vitamin E daily for three to six months, and followed carefully by repeated examinations, electrocardiograms and orthodiagrams.

We believe that so much harm has resulted, and the public has been mulcted of so much money, that we should call attention to the adverse conclusions published concerning the use of vitamin E in heart disease.

Samuel Baer, M.D.
William I. Heine, M.D.
Philadelphia.

NEOSTIGMINE AS ANTIDOTE TO ETAMON®

To the Editor:—The publication of a report by Drs. Lasser, Rosenthal and Loewe of a death following the use of tetraethylammonium chloride (etamon chloride®) in The Journal of January 15, page 153, makes it seem advisable to call attention to the means available for controlling the effects of this drug with neostigmine (prostigmine®). It happened that such interruption of the effects of etamon® by neostigmine was mentioned in the report of the Council on Pharmacy and Chemistry which followed immediately the case report referred to above (Grimson, K. S.; Hendrix, J. P., and Reardon, M. J.: J. A. M. A. 139: 154 [Jan. 15] 1949).

Tetraethylammonium chloride now is in widespread use, and it is to be expected that occasional severe reactions in the form of vascular collapse, as previously reported, will occur. This drug blocks the transmission of nerve impulses through autonomic ganglions, and among other effects, loss of vasomotor tone results. The blockade presumably is brought about by interfering with the action of acetylcholine, which is believed to be the chemical mediator for the transmission of such impulses through the ganglions. Tetraethylammonium chloride resembles curare in its action except that the effects of curare are chiefly on the transmission of nerve impulses to striated muscle, while those of tetraethylammonium chloride in usual dosage are principally on autonomic ganglions. The antagonism of the effects of curare by neostigmine is well known.

In the course of animal experiments with tetraethylammonium chloride it was noted that the ganglionic blockade could be relieved with neostigmine. Observations on patients also indicated that the major effects of the drug were cancelled promptly by 0.5 to 1.0 mg. of neostigmine intravenously (Reardon, M. J.; Marzoni, F. A., and Hendrix, J. P.: *Federation Proc.* 6: 364, 1947). A more detailed report is in preparation.

We fortunately have not had occasion to deal with severe vascular collapse from tetraethylammonium chloride and therefore have not given neostigmine under such circumstances. However, it was used effectively in several cases by Page and co-workers (*Am. J. M. Sc.* 213: 572 [May] 1947). Mention of the antidotal effects of neostigmine is made in the manufacturer's circular which accompanies vials of etamon® solution.

Some disagreeable effects of neostigmine may be experienced, such as intestinal cramps, but these may be controlled readily with atropine.

Epinephrine usually is recommended for hypotension following tetraethylammonium chloride, but neostigmine is a more complete and more physiologic antidote. In addition, epinephrine produces tachycardia and the patient is sensitized to its effects by the action of tetraethylammonium chloride (Moe, G. K.: J. A. M. A. 137:1115 [July 24] 1948). If dangerous hypotension is encountered after use of tetraethylammonium chloride, it should be treated promptly, lest the shocklike state become irreversible, as apparently occurred in the case mentioned in the first paragraph.

It must be recognized that tetraethylammonium chloride is a potent as well as useful drug, capable of producing profound physiologic effects. Due caution must be exercised in its use, especially intravenously, and it is advisable to have neostigmine at hand when it is so injected.

James P. Hendrix, M.D.
Durham, N. C.

OCCUPATIONAL DERMATITIS, DISEASE OR INJURY?

To the Editor: At the recent meeting of the American Academy of Dermatology and Syphilology, while presiding over the course on occupational dermatology, I was repeatedly told by physicians from Southern and Midwestern states that occupational dermatitis was considered a disease in their states and that a worker suffering from a disease was not compensated.

Industrial commissions throughout the country are apt to reject diseases as being compensable. They must be convinced that the disease arises from an injury occurring out of and in the course of the worker's employment. They readily accept abrasions of the skin with secondary infection, bruises, burns, cuts and lacerated wounds, because these conditions are not classified as diseases, but as injuries.

As the large majority of occupational skin disturbances are the result of the same factors, mechanical, physical and chemical, it behooves the physician and dermatologist to label them as injuries of the skin, and not dignify them by the classification occupational diseases.

For years all authors have startled the country by stating that occupational dermatoses comprise 60 per cent, or more, of the occupational diseases. In Massachusetts in 1939 there were 169 cases of occupational disease reported, of which 130 were cases of dermatitis. If we include injury from chrome, this figure would reach 136. For the year ending June 30, 1948, the Massachusetts Department of Labor and Industries reports a total of 268 cases of occupational disease, with 234 cases of occupational dermatitis. Of course this figure is only a small percentage of industrial dermatoses, for many of them are not reported. In the year ending June 30, 1948, I alone saw more than 234 cases of industrial eruptions, and reported only the few about which I received a form from the Massachusetts Department of Labor and Industries.

In Massachusetts the department may require every physician treating a patient whom he believes to be suffering from any ailment or disease contracted as a result of the nature, circumstances or conditions of the patient's employment to report such information relating thereto as it may require, within such time as it may fix, and it may issue a list of such diseases which shall be regularly reported on by physicians, and may add to or change such list at any time. The department will pay a fee of 50 cents for each such report (Gen. Laws. Ter. Ed., Chapter 149, Sec. 11).

Few physicians comply with this request unless they receive the aforementioned form; hence these statistics are of little value. The ordinary burn or injury to the skin responds readily to treatment, often is not disabling or of short disability, and hence is considered of little importance.

These cases of occupational eruptions of the skin should be considered as mechanical, physical or chemical injuries, and not as diseases.

J. G. Downing, M.D., Boston.

PENICILLIN AND MALARIA

To the Editor: I was surprised at the haste with which Dr. Saunders rushed to your columns in the issue of Oct. 9, 1948, page 449, to comment on the abstract of my paper, entitled "Treatment of Relapsing Malaria with Specific Antimalarial Drugs in Combination with Penicillin," The Journal, Aug. 28, 1948, page 1632. Had he only waited to go over the reprint, which is already posted to him on request, he would have, perhaps, chosen not to write the letter posthaste.

I have already stated in my paper that penicillin has no effect on inoculation malaria as shown by Hindle and others (1945) in the treatment of cases of neurosyphilis by "malaria therapy." Here the malarial bouts are not affected because, as I presume, penicillin has no action on malarial parasites in peripheral blood.

Dr. Saunders mentions patients with relapsing malaria who were given penicillin for other conditions and concludes from the results that "there is evidence to prove that penicillin has no effect on malaria." His conclusion is unwarranted because, according to my thesis, penicillin will act only on the preerythrocytic stage and not on the peripheral stage of the parasites. To control relapses, it is necessary to attack the parasite in preerythrocytic stage by penicillin and that in the peripheral blood by the usual antimalarial drugs.

My further work on the lines of my paper is lending strong support to my hypothesis as judged by the clinical results obtained, and it will be interesting to know the results of the therapy abroad.

P. L. Deshmukh, M.D.,
Sassoon Hospitals, Poona City, Indian Dom.

MIGRAINE

To the Editor: The article on migraine by Marcussen and Wolff, The Journal, January 22, page 198, demonstrates the reluctance of the medical profession to adopt new methods of approach, even for a disease in which our therapy has been notoriously inadequate. No reference is made to allergic management of migraine, the efficacy of which has been thoroughly established for many years.

Most clinicians who have availed themselves of this method agree that complete cessation of symptoms from elimination procedures as well as from desensitization treatment is a common occurrence. In my own experience, I rarely fail to obtain conclusive skin reactions from intradermal skin testing in true migraine. Many patients with seasonal migraine respond to hyposensitization therapy with pollen and fungous extracts as promptly as do hay fever patients. Such medications as intravenously administered aminophylline, as well as antihistaminics administered orally or intravenously, compare favorably with ergotamine tartrate in relieving migraine. The "Sunday headache" mentioned by the authors parallels our experience with the "Sunday asthma" or "Sunday hives" from sensitivity to food or beverages consumed on Saturday night or from change of the patient's surroundings over the weekend.

In view of the somewhat discouraging outlook suggested by their paper on nonallergic management, some reference to this different approach should have been made. Moreover, there is always the great danger of treating a disease on a psychosomatic basis because we are unable to understand its mechanism.

George L. Waldbott, M.D., Detroit.

Council on Medical Education and Hospitals

NEW HOSPITALS REGISTERED

The following hospitals were registered by the Council on Medical Education and Hospitals of the American Medical Association at its meeting in Chicago, Feb. 8, 1949:

Pineview Manor for Handicapped Infants and Children	Montgomery Ala.
Maricopa County Hospital	Phoenix, Ariz.
Fincher Clinic and Hospital	El Dorado, Ark.
City Hospital	Siloam Springs, Ark.
Southwest Memorial Hospital	Cortez, Colo.
Franklin County Hospital	Apalachicola, Fla.
Sugarland Hospital	Clewiston, Fla.
Charlotte Hospital	Punta Gorda, Fla.
Palmetto Medical Clinic-Hospital	Wauchula, Fla.
Veterans Admin. Hospital	Dublin, Ga.
Cole Hospital	Champaign, Ill.
Dr. *J. A.* Phillips Hospital	Minden, La.
International Falls Memorial Hosp.	International Falls, Minn.
Natchez General Hospital	Natchez, Miss.
Hart Clinic-Hospital	Salem, Mo.
Maynard Municipal Hospital	Red Cloud, Neb.
Brunswick General Hospital	Amityville, N. Y.
Crippled Children's Guild Hospital	Buffalo, N. Y.
Chowan Hospital	Edenton, N. C.
Lorenzen Memorial Hospital	Elgin, N. Dak.
Memorial Hospital	Hazen, N. Dak.
Shadyside Hospital	North Canton, Ohio
Grande Ronde Hospital	La Grande, Ore.
Henderson County Memorial Hospital	Athens, Texas
Oak Ridge Sanitarium	Austin, Texas
San Jacinto Memorial Hospital	Baytown, Texas
Palms Nursing Home	Beaumont, Texas
Allen Hospital	Burnet, Texas
Seyler Clinic and Hospital	Commerce, Texas
Ghormley Clinic-Hospital	Corpus Christi, Texas
Hamilton Clinic and Hospital	Hamilton, Texas
Medical Arts Hospital	Harlingen, Texas
Clay County Memorial Hospital	Henrietta, Texas
Medina Hospital	Hondo, Texas
Livingston Hospital	Livingston, Texas
Overton Memorial Hospital	Overton, Texas
Hunter-Hunter and Kay Clinic-Hospital	Palestine, Texas
Rising Star Hospital	Rising Star, Texas

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: *Parts I and II.* Various Centers. June 20-22, Sept. 12-14. *Part II.* April 25-26. Exec. Sec., Mr. E. S. Elwood, 225 S. 15th St., Philadelphia 2.

EXAMINING BOARDS IN SPECIALTIES

American Board of Anesthesiology, Inc. *Written.* Various Centers. July 15: Final date for filing application is April 15. *Oral.* April 10-14 and Oct. 16-20. Sec., Dr. Curtiss B. Hickcox, 745 Fifth Ave., New York 27.

American Board of Dermatology and Syphilology: *Oral.* New York City, April 1-3. Sec., Dr. George M. Lewis, 66 East 66th Street, New York 21.

American Board of Internal Medicine: *Oral.* New York City, March 23-25. Philadelphia, June 1-3. *Written.* Oct. 17. Final date for filing application is May 1. Asst. Sec.-Treas., Dr. W. A. Werrell, 1 Main St., Madison 3, Wis.

American Board of Neurological Surgery: *Oral.* Chicago, June 1949. Sec., Dr. W. J. German, 310 Cedar Street, New Haven, Conn.

American Board of Obstetrics and Gynecology, Inc.: *Oral.* Chicago, May 8-14. Final date for filing application is April 1. Sec., Dr. Paul Titus, 1015 Highland Building, Pittsburgh 6.

American Board of Ophthalmology: *Oral.* San Francisco, March 21-24; New York, June 11-15; St. Louis, Oct. 15-19; Boston Dec. Sec., Dr. S. J. Beach, 56 Ivie Rd., Cape Cottage, Maine.

American Board of Orthopaedic Surgery. *Part I.* New York City, April *22-23*; Atlanta, Ga., April *29-30*; Indianapolis, May *6-7* and Denver, May 13-14. *Part II.* New York City, Jan. 1950. Final date for filing application for Part II is Aug. 15. Address: Dr. Francis M. McKeever, 1136 W. 6th St., Los Angeles 14, Calif.

American Board of Otolaryngology: New York, May 11-14; Chicago, Oct. 4-7. Sec., Dr. D. M. Lierle, University Hospital, Iowa City.

American Board of Pathology: Boston, April 12-13. Final date for filing application is March 15. Sec., Dr. Robert A. Moore, 507 S. Euclid Ave., St. Louis 10, Mo.

American Board of Pediatrics: *Oral.* Baltimore, May 7-9. Exec. Sec., Dr. John McK. Mitchell, 6 Cushman Rd., Rosemont, Pa.

American Board of Physical Medicine: Atlantic City, June 4-5. Final date for filing application is March 15. Sec., Dr. R. L. Bennett, 30 N. Michigan Blvd., Chicago.

American Board of Plastic Surgery: Examinations are given in June and November of each year in the home town of applicants. Sec., Treas., Dr. Louis T. Byars, 400 Metropolitan Bldg., St. Louis, Mo.

American Board of Psychiatry and Neurology, Inc. December, New York City. Sec., Dr. F. J. Braceland, 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Radiology. Atlantic City, June 2-4. Sec., Dr. B. R. Kirklin, 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Surgery. *Written.* Various Centers, March and October. *Final date for filing application for October examination* is July 1. Sec., Dr. J. Stewart Rodman, 225 S. 15th St., Philadelphia.

American Board of Urology: Feb. 1950. Sec., Dr. Harry Culver, 7935 Sunnyside Road, Minneapolis 18, Minn.

BOARDS OF MEDICAL EXAMINERS

Alabama: *Examination.* Montgomery, June 28-30. Sec., Dr. D. G. Gill, 519 Dexter Ave., Montgomery.

Arkansas: * Little Rock, June 9-10. Sec., Dr. L. J. Kosminsky, Texarkana. *Eclectic.* Little Rock, June 9-10. Sec., Dr. C. H. Young, 1415 Main St., Little Rock.

California: *Examination.* San Francisco, June 20-23. Sec., Dr. Frederick N. Scatena, 1020 N St., Sacramento.

Colorado: * *Endorsement,* Denver., April 5. *Written,* Denver, June 20-22. Sec., Dr. W. W. King, 831 Republic Bldg., Denver 2.

Delaware: Dover, July 12-14. Sec., Dr. J. S. McDaniel, 229 South State St., Dover.

District of Columbia: * *Reciprocity,* Washington, March 14. *Written,* Washington, May 9-10. Sec., Dr. George C. Ruhland, 4130 Municipal Bldg., Washington.

Florida: * *Examination,* Jacksonville, June 26-28. Sec., Dr. Frank D. Gray, 12 N. Rosalind Ave., Orlando.

Georgia: *Examination.* June, Atlanta and Augusta. *Reciprocity.* Atlanta, June. Sec., Mr. R. C. Coleman, 111 State Capitol, Atlanta.

Guam: *Endorsement.* Agana, Last Friday of each month. Sec., Capt. C. K. Youngkin, Dept. of Public Health, Guam, % F.P.O. San Francisco, Calif

Hawaii: * *Examination.* Honolulu, July 11-14. Sec., Dr. S. E. Doolittle, 881 S. Hotel St., Honolulu.

Idaho: Boise, July 11-13. Sec., Miss Estella S. Mulliner, Bureau of Occupational Licenses, 355 State House, Boise.

Illinois: Chicago, April 12-14. Supt. of Registration, Mr. Fred W. Ruegg, Capitol Bldg., Springfield.

Indiana: *Examination.* Indianapolis, June 21-23. Sec. Board of Medical Registration and Examination. Dr. Paul R. Tindall, 416 K. of P. Bldg., Indianapolis.

Iowa: * *Examination,* Iowa City, June 13-15. Sec., Dr. M. A. Royal, 506 Fleming Bldg., Des Moines.

Kansas: Kansas City, June 1-2. Sec., J. F. Hassig, 905 North 7th St., Kansas City, Kans.

Kentucky: *Examination.* Louisville, June 15-17. Sec., Dr. Bruce Underwood, 620 S. 3rd St., Louisville 2.

Maryland: *Examination.* Baltimore, June 21-24. Sec., Dr. Lewis P. Gundry, 1215 Cathedral St., Baltimore. *Homeopathic.* Baltimore, June 14-15. Sec., Dr. John A. Evans, 612 West 40th St., Baltimore.

Minnesota: * Minneapolis, April 19-21. Sec., Dr. J. F. Du Bois, 230 Lowry Medical Arts Bldg., St. Paul 2.

Mississippi: Jackson, June 21-22. Asst. Sec., Dr. R. N. Whitfield, State Board of Health, Jackson.

Missouri: *Examination.* St. Louis, May 30-31 and June 8-10. Exec. Sec., Mr. John A. Hailey, Box 4, Jefferson City.

Montana: Helena, April 4-6. Sec., Dr. O. G. Klein, First National Bank Building, Helena.

Nebraska: * *Examination.* Omaha, June. Dir., Bureau of Examining Boards, Mr. Oscar F. Humble, 1009 State Capitol Building, Lincoln 9.

Nevada: Carson City, May 2. Sec., Dr. G. H. Ross, 112 N. Curry Street, Carson City.

New Jersey: *Examination.* Trenton, June 21-24. Sec., Dr. E. H. Hallinger, 28 West State Street, Trenton 8.

New Mexico: * Santa Fe, April 11-12. Sec., Dr. V. E. Berchtold, 141 Palace Ave., Santa Fe.

New York: Albany, Buffalo, New York and Syracue, June 28-July 1, Sec., Dr. Jacob L. Lochner, 23 South Pearl St., Albany.

North Carolina: *Endorsement.* Pinehurst, May 9. *Examination.* Raleigh, June 23-25. Sec., Dr. Ivan Procter, 226 Hillsboro St., Raleigh.

Ohio: *Endorsement.* Columbus, April 5. *Written.* Columbus, June. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.

Oregon: * *Endorsement.* Portland, April 29-30. *Examination.* Portland, July. Exec. Sec., Mr. Howard I. Bobbitt, 609 Failing Bldg., Portland.

Pennsylvania: *Examination.* Philadelphia and Pittsburgh, July. Acting Sec., Mrs. B. G. Steiner, 351 Education Bldg., Harrisburg.

Rhode Island: * *Examination.* Providence, April 7-8. Chief, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

South Carolina: *Examination.* Columbia, June 27-29. *Endorsement.* Columbia, March 7, April 4, May 2, June 27-28, Aug. 1, Sept. 5 and Oct. 3. Sec., Dr. N. B. Heyward, 1329 Blanding St., Columbia.

South Dakota: * *Examination.* Pierre, July 19. Sec., Dr. G. J. Van Heuvelen, Capitol Bldg., Pierre.

Tennessee: * *Examination.* Memphis, March 23-24. Sec., Dr. H. W. Qualls, 1635 Exchange Bldg., Memphis.

Texas: *Examination.* Austin, June 16-18. Sec., Dr. M. H. Crabb, 209 Medical Arts Bldg., Fort Worth 2.

Utah: *Examination.* Salt Lake City, July. Sec., Dept. of Registration, Miss Rena B. Loomis, 324 State Capitol Bldg., Salt Lake City.

Virginia: *Examination.* Richmond, June 17-18. *Reciprocity.* Richmond. June 16. Dr. K. D Graves, 631 First St., S.W., Roanoke.

Washington: * Seattle, July. Sec., Mr. Edward C. Dohm, Department of Licenses, Olympia.

West Virginia: Charleston, April 7-9. Sec., Dr. N. H. Dyer, State Capitol, Charleston 5.

Wisconsin: * *Examination.* Milwaukee, June 28-30. Sec., Dr. C. A. Dawson, Tremont Bldg., River Falls.

Wyoming: Cheyenne, June 6. Sec., Dr. Franklin D. Yoder, Capitol Bldg., Cheyenne.

---

* Basic Science Certificate required

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

ARIZONA: *Examination.* Tucson, March 15. Sec., Dr. Francis A. Roy, Science Hall, University of Arizona, Tucson.

ARKANSAS: *Examination.* Little Rock, May 3. Sec., Mr. L. E. Gebauer, 1002 Donaghey Bldg., Little Rock.

COLORADO: *Examination.* Denver, June 1-2. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver.

DISTRICT OF COLUMBIA: *Examination.* Washington, April 18-19. Sec., Dr. George C. Ruhland, 4130 Municipal Bldg., East, Washington.

FLORIDA: *Examination.* Gainesville, June 11. Sec., Mr. M. W. Emmel, University of Florida, Gainesville.

IOWA: *Examination.* Des Moines, April 12. Sec., Dr. Ben H. Peterson, Coe College, Cedar Rapids.

MICHIGAN: *Examination.* Detroit and Ann Arbor, May 13-14. Sec., Miss Eloise LeBeau, 101 N. Walnut St., Lansing 15.

MINNESOTA: *Examination.* April 4, June and Oct. Sec.-Treas., Dr. Raymond N. Bieter, 105 Millard Hall, Univ. of Minnesota, Minneapolis.

NEW MEXICO: *Examination.* Santa Fe, March 20. Sec., Miss Marguerite Kilkenny, 110 W. Houghton St., Santa Fe.

OKLAHOMA: April 15. Sec., Dr. Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

OREGON: Portland, June 18, Sept. 3 and Dec. 3. Sec., Mr. Charles D. Byrne, State Board of Higher Education, Eugene.

SOUTH DAKOTA: Vermillion, June 3-4. Dr. G. M. Evans, 310 E. 15th St., Yankton.

TENNESSEE: Memphis, March 21-22 and July 8-9. Sec., Dr. O. W. Hyman, 874 Union Ave., Memphis 3.

WISCONSIN: Madison, April 2.. Milwaukee, June 4. Sec., Prof. W. H. Barber, Ripon College, Ripon.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Medical Practice Acts: Revocation of License Following Release From Probation.—The plaintiff filed a petition for a writ of mandate to compel the defendant board of medical examiners to set aside its order suspending him from practicing medicine in California. From a judgment denying the petition, the plaintiff appealed to the district court of appeals, second district, division 2, California.

The plaintiff was granted a license to practice medicine and surgery in California in 1938. In 1947, following a plea of guilty, he was convicted of a violation of the state health and safety code prohibiting a person from purchasing for or administering or dispensing a narcotic to an addict except under certain circumstances. After completing one half of the probationary period fixed by the court the plaintiff filed a motion, in accordance with the provisions of the penal code, to terminate his probation and dismiss the accusation against him. This motion was granted. The defendant board, however, on March 15, 1948, after receiving a certified copy of the court order, concluded that the order dismissing the information did not "remove or wipe out" the conviction suffered by the plaintiff. It then found that the plaintiff had been convicted of "an offense involving moral turpitude" and by reason of his conviction was "guilty of unprofessional conduct" and therefore ordered the plaintiff's suspension.

It was contended by the plaintiff that inasmuch as the Board had elected to base its decision solely on the plaintiff's prior conviction its action in suspending his license was an improper imposition of a penalty after he had been "released from all penalties and disabilities resulting from the offense." The penal code under which the court terminated the plaintiff's probation provided that after such a termination the defendant shall "be released from all penalties and disabilities resulting from the offense or crime of which he has been convicted." On the basis of the provisions of this section, the language of which in the court's opinion was plain and unequivocal, the district court of appeals held that a discharged probationer was by virtue of such section "released from all penalties and disabilities resulting from the offense or crime of which he has been convicted" and that the medical board did not have jurisdiction, after the plaintiff's discharge, to penalize him because of his conviction. The judgment of the trial court denying the plaintiff's petition for a writ of mandate was therefore reversed.—*Meyer v. Board of Medical Examiners 200 P. (2d) 128 (California 1948).*

Medical Motion Pictures

FILM REVIEWS

Management of the Failing Heart. 16 mm., color, sound, 1,300 feet (1 reel), showing time forty minutes. Prepared in 1948 by the Department of Pharmacology, Cornell University Medical College, New York. Produced by Joseph P. Hackel, New York, through a grant for Postgraduate Instruction by Varick Pharmacal Company, Inc., Division of E. Fougera & Company, Inc., New York. Procurable on loan from The Medical Film Guild, 167 West Fifty-Seventh Street, New York 19.

This motion picture describes the treatment of congestive heart failure used at Cornell University. The first part of the film deals with physiology, illustrating basic principles. Animated charts and diagrams are utilized to depict congestion in the pulmonary and peripheral circulation. A case of paroxysmal nocturnal dyspnea shown gives an active but not professionally convincing portrayal of the condition.

Unfortunately, the statement "Digitalis Nativelle is the drug of choice for cardiac decompensation" is of course, untrue, and because of it the film is definitely labeled as a commercial production. The reference to varying degrees of decompensation, or some conditions in which digitalis is notoriously dangerous—for example, in greatly enlarged hearts, large cardiac infarcts with slight decompensation and possibly in high grade heart block with heart rates in the middle twenties—is omitted. It would have been appropriate to mention the hazards of overdigitalization at the same time that the dosage was compared with that of ordinary digitalis and also to have mentioned that nausea cannot be used as an early sign. It is also unfortunate that the single dose method of digitalization is recommended, since only rarely is it necessary; the divided dose method is recognized by most cardiologists.

The common misconception of overrestriction of water is handled poorly, since the adequate amount of fluids is not given; however, the subject of salt-free diet and the physiology are well illustrated.

The film is on a medical student level, but could prove beneficial to physicians who are not familiar with the current conceptions of the management of disturbed water balance causing edema.

The photography is excellent. The animation and narration are satisfactory. The film is well organized.

The Epidemiology of Murine Typhus. 16 mm., black and white, sound, 665 feet (1 reel), showing time eighteen minutes. Produced in 1948 by and procurable on loan from United States Public Health Service, Communicable Disease Center, 605 Volunteer Building, Atlanta 3.

This motion picture is the first of a series on epidemiology of infectious diseases. It depicts the three elements of murine typhus epidemiology, namely, the animal reservoir (rats), the vector (rat fleas) and man. Infectious rats in their common environments are shown. A case of typhus due to infectious rats is shown together with suggestions for management of the problem.

Human incidence is portrayed by seasonal variation, age, sex and social status distribution. The geographic distribution in the United States is emphasized by animated maps covering five year periods to date. The character of the infection is demonstrated by the rat reservoir, the maintenance of infection and the mode of transmission of the disease to human beings by means of a vector. The relation of the vector to the rat reservoir and to human beings, as well as the effect of seasonal changes on its activity, is described.

The doctor's responsibility in the control of the disease includes clinical diagnosis, confirmation by serologic data and prompt reporting to the local Health Agency. The epidemiologist investigates the case, analyzes the data and institutes effective control measures, such as DDT dusting, rat poisoning and ratproofing buildings.

This is an excellent teaching film for clinicians, public health workers and medical students. Since the film is scientifically accurate and is done in a simple manner, it is also suitable for classes in nursing education.

The photography, drawings and charts are excellent. From a production point of view, the film is well done.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1938 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Histopathologic Effects of Nitrogen Mustard Therapy upon Normal and Neoplastic Hematopoietic Tissues. M. Block, C. L. Spurr, L. O. Jacobsen and T. R. Smith.—p. 671.
Interpretation of Rh Antibodies. I. Davidsohn and K. Stern.—p. 690.
*Massive Necrosis of Liver Following Exchange Transfusion for Erythroblastosis Fetalis. P. Rosenblatt.—p. 700.
Significance of Hr Sensitization in Rh Antibody Determinations. R. T. Fisk and A. F. Brown.—p. 716.

Necrosis of Liver Following Exchange Transfusion for Erythroblastosis Fetalis.—In exchange or substitution transfusion for erythroblastosis fetalis the blood of an erythroblastotic infant is drained and simultaneously replaced by citrated compatible donor's blood. The total amount of blood used varies from 500 to 1,000 cc. By this procedure, and sometimes by the additional help of heparin as an anticoagulant, the operation has been speeded so that a 90 per cent exchange of blood may be effected in about ninety minutes. Rosenblatt reports the necropsy findings in 3 infants who died after such exchange transfusions. The lesions were strikingly different from those ordinarily seen in erythroblastosis fetalis. The diagnosis had been made antenatally by means of serologic tests, the pregnancies were terminated by cesarean section before term and the babies were immediately given transfusions by the exchange or substitution technic. The infants lived from one to five days; at necropsy, all showed massive liver necrosis, and 2 of the infants also showed focal necrotic lesions in the adrenals. It is considered that a combination of the following factors may have been responsible for these untoward findings: (1) the presence of erythroblastosis; (2) the administration of excessive amounts of sodium citrate and/or calcium gluconate in the transfused blood, and (3) excessive speed of transfusion. While the exchange transfusion may be a valuable adjunct in the treatment of erythroblastosis fetalis, in view of the described lesions, it must be considered an unsafe procedure as given at the present time. The use of heparinized blood, rather than citrated blood, is suggested. It is also suggested that the rate of effecting the exchange transfusion be slowed.

Tests of Pancreatic Function. — Popper and Necheles show that the older tests of pancreatic function were based on the complete absence of pancreatic juice in the intestinal tract or on vague indirect determinations. These tests, except the stool test, are not in use any longer. The tests which are in use nowadays are: (1) examination of the stools for excessive elimination of undigested fat and undigested muscle fibers which, with certain reservations, are suggestive of pancreatic deficiency; (2) determination of serum amylase and lipase which are reliable indicators of acute pancreatitis; (3) determination of the fasting blood sugar and of glucose tolerance curves, especially after double glucose administration, which will reveal disorders of the pancreas that involve also the insular tissue; this is of special significance in acute and subacute pancreatitis, possibly in sclerosing pancreatitis and in some forms of carcinoma, and (4) Agren and Lagerlöf's secretin test with simultaneous intubation of stomach and duodenum and with aspiration of most of the pancreatic secretion, the first procedure which gives reliable information about the external secretory function of the pancreas. It is to be hoped that it will come into general use. The authors have developed a pancreatic function test in animal experiments which, by demonstrating an increase of pancreatic enzymes in the blood after moderate stimulation of the pancreas, indicates obstruction to pancreatic secretion or, by revealing the absence of such an increase after vigorous stimulation, shows a secretory deficiency of the pancreas. The clinical usefulness of this test still remains to be proved.

Chronic Constrictive Pericarditis.—Paul and his coworkers report 53 patients, 36 men and 17 women, with chronic constrictive pericarditis. Thirty-seven (70 per cent) of these patients were between the ages of 10 and 40 years. Shortness of breath on effort was the commonest symptom, followed by swelling of the ankles and legs, abdominal swelling and abdominal discomfort. The commonest physical observations were enlargement of the liver, prominence of the veins of the neck, ascites, peripheral edema and signs of fluid and/or pleural thickening at the lung bases. Cardiac enlargement was revealed on roentgenologic examination in 29 patients, and cardiac pulsations were observed on fluoroscopy to be diminished in 32 of 40 patients. Chest films disclosed evidence of unilateral or bilateral hydrothorax in 28 patients. Calcification of the pericardium was observed in 29 patients. Electrocardiograms showed auricular flutter or fibrillation in 20 patients, low voltage in 17 and abnormal T waves in the limb leads in 45. Surgical exploration with pericardiolysis and partial pericardiectomy was performed on 42 of this group. Results in 25 have been satisfactory. Sixteen patients died, 6 as a result of the operative procedure itself, 5 from complicating diseases and 4 from the effect of their underlying disease; in 1 patient the cause of death is not known. Necropsies revealed an abnormal liver in all 16. Seven of the 11 patients not operated on were too ill for surgery and died while receiving medical treatment. Causation was entirely obscure in 30 cases despite availability of sections of the pericardium for microscopic study in 46 of the 53 patients. Tuberculous involvement of the pericardium was proved in 9. Six had a history of acute pericarditis of unknown origin, and in 3 others the history was suggestive of an episode of acute pericarditis in the past.

Constrictive Pericarditis Over Left Heart Chambers.—White and his co-workers report 3 young men with chronic constrictive pericarditis involving preponderantly the left heart chambers. The first patient died from complications of peripheral arterial embolism after two unsuccessful pericardial resections carried out by anterior approach and an omentopexy. The other 2 patients were greatly benefited as a result of a transthoracic approach allowing free exposure of the side and back of the heart. The pericardium was removed from the left auricle and left ventricle in these patients. In the first of these 2 patients two previous operations through the usual anterior approach had been unsuccessful. In all 3 patients diagnosis was suggested by the clinical evidence of accentuation of the pulmonary second sound, cardiac enlargement involving the right ventricle and a shift of the electrocardiographic axis deviation to the right, with a persistence of chronic congestion. Measurement of the pulmonary blood pressure by cardiac catheterization has been of considerable aid in localization of the site of the constriction in the last 2 cases, confirming by its marked elevation the constriction of the left heart chambers, which has acted like mitral stenosis on the pulmonary circulation and right side of the heart.

Penicillin in Anthrax.—LaBoccetta treated 36 patients, 21 men and 15 women, with uncomplicated cutaneous anthrax, with sodium penicillin solution. Except for the first 3 patients, who received penicillin intravenously, the drug was administered intramuscularly. The majority of the patients in this group were given between 100,000 to 200,000 units in a twenty-four hour period at three-hourly intervals. In many patients the lesions continued to spread and the edema increased for twenty-four to thirty-six hours after treatment was begun. Penicillin apparently has no direct or immediate effect on the tissue-damaging factor of cutaneous anthrax. Bacteriologic confirmation of the diagnosis was obtained in 30 patients. Nine of these became bacteriologically negative twenty-four hours after treatment was instituted. Nine other patients became negative after forty-eight hours, and an equal number after seventy-two hours of penicillin treatment. In most cases the lesions were regressing after the smears and cultures became negative on two successive days, at which time treatment was discontinued. There were no untoward reactions to penicillin to warrant cessation of its administration. Penicillin by intramuscular route may be used safely and successfully in the treatment of cutaneous anthrax.

Analysis of Ocular Motor Anomalies. W. C. Owens.—p. 1297.

Use of Immune Globulin in Uveitis.—According to Kronenberg clinical interest in gamma globulin lies in the fact that many of the antibodies elaborated by the defense mechanisms of the body are concentrated in this fraction. The theory on which the author instituted the injections of immune globulin is based on the fact that the organism requires antibodies to combat infection. In the treatment of uveitis, the function of foreign proteins is to stimulate the production of antibodies within the organism itself. It seemed logical, therefore, that the patient would obtain greater help in combating the infection if antibodies were supplied directly by injections. For this reason, the author used injections of concentrated immune globulin containing both bacterial and virus antibodies. Encouraging results have been obtained in the treatment of 6 cases of various forms of uveitis by injections of massive doses of immune globulin in conjunction with the use of foreign protein. Three of these cases are reported.

Traumatic Bronchial Rupture with Occlusion.—According to Hodes and his co-workers bronchial tears are usually due to crushing chest injuries, and are often fatal. When patients survive this injury, complete bronchial occlusion and pulmonary collapse may develop. A patient who sustained a torn bronchus with subsequent pulmonary collapse was recently treated in the Hospital of the University of Pennsylvania. The authors describe their observations on this patient. Literature contains reports on 32 patients. Of these, 10 survived the immediate effect of their injury and experienced bronchial occlusion. In every instance, the bronchial defect lay immediately adjacent to or within a few centimeters of the bifurcation of the trachea. When chest injuries cause tears in the main bronchi close to the tracheal bifurcation, the patient usually reveals shock, dyspnea, anoxia, interstitial emphysema and cough. Routine roentgenograms of the chest immediately after injury may reveal fractured ribs, interstitial emphysema, pneumothorax, pulmonary compression and mediastinal shift. Later, when bronchial occlusion is complete, the classical roentgen manifestations of pulmonary collapse develop. Bronchograms reveal a cup-shaped blind pouch at the site of the occlusion. Substernal distress and dyspnea occur commonly in patients with post-traumatic bronchial occlusion.

Pulmonary Embolism Without Infarction.—Shapiro and Rigler direct attention to the fact that pulmonary embolism may occur without infarction owing to the double circulation of the lungs through the bronchial and pulmonary vessels. The former are concerned with the nutrition of the lungs, while the latter are actively engaged in the respiratory exchange of gases. There are abundant anastomoses between the two. Many roentgenologists still associate pulmonary embolism with an area of increased density in the roentgenogram. The authors present 3 cases of pulmonary embolism without infarction which were confirmed at necropsy. They stress that in pulmonary embolism without infarction the characteristic roentgen findings are increased radiability and ischemia of the involved pulmonary segment. Abrupt termination of the embolic pulmonary artery is also frequently demonstrable. This contrasts strikingly with the usual area of increased density on the roentgenogram found in cases of embolism with infarction.

Nonspecific Enterocolitis.—Olsan and Sussman observed at necropsy a number of cases of enteritis that presented unusual features. They present 1 case of apparent chronic granulomatous jejunoileitis which at postmortem examination five years later showed no evidence of this disease. There was, however, enterocolitis of undetermined nature. The lesion in the large intestine was classified as ulcerative colitis. Chronic granulomatous disease of the small intestine until now has been considered to be characterized by stenosis. This case indicates the possibility that resolution without stenosis might take place. The alternative explanation is a disease, possibly a variety of ulcerative colitis, in which the lesion of the small intestine dominated the roentgen findings, passing through a phase of thickening and rigidity to a normal wall. Two cases of granulomatous jejunoileitis and one of ulcerative colitis with amyloidosis are reported. It is suggested that amyloidosis in chronic enteritis is more frequent than has been suspected and might account, in part at least, for the clinical and roentgenographic findings in occasional cases of granulomatous disease. A review of the literature also suggests the possibility that some cases considered primary amyloidosis might be instances of amyloidosis secondary to chronic enteritis. Five cases are reported of extensive involvement of jejunum and ileum in ulcerative colitis. Thus the roentgen appearance of stenosis in the small intestine does not necessarily indicate granulomatous disease. Even in the absence of disease of the terminal ileum, ulcerative colitis cannot be excluded despite the lack of distinct roentgen evidence to indicate its presence in the large intestine. Presumably the small intestinal deformity is due to edema and infiltration without significant fibrosis. These observations indicate that it is difficult to determine the type of enterocolitis from the roentgen appearance alone, and that even with postmortem data the pathogenesis may not be ascertainable.

Systemic Administration of Bacitracin in Surgical Infections.—According to Meleney and his associates, bacitracin is an antibiotic produced by the Tracey strain of Bacillus subtilis. During the past twenty months, purification and standardization have reached a point whcih has permitted the systematic use of bacitracin. Studies are being carried out by different groups. Bacitracin has a wide antibacterial spectrum. It may be used systemically as well as locally in surgical infections. This report presents the results obtained with the systemic administration of bacitracin in 105 cases of surgical infection. For the most part they were cases which had failed to respond to the sulfonamide compounds and to the other antibiotics. There was an over-all favorable response in about 70 per cent of these cases, and in about one fifth of these the results were dramatic. Of particular interest were 3 cases of extensive progressive bacterial synergistic gangrene, in all of which the patients responded within seventy-two hours and recovered with surgical excision. In the three largest groups, namely, cellulitis, deep abscess and infected accidental wound, favorable results were obtained in three fourths of the cases. In the dramatic group, the causative organisms were for the most part in the staphylococcus and streptococcus groups. In the latter classification were found hemolytic, nonhemolytic, microaerophilic and anaerobic streptococci. In a considerable number of staphylococcus strains the authors found resistance to penicillin and susceptibility to bacitracin. In 14 per cent of the cases the results were questionable, and in a slightly higher percentage the results were frankly nil. In most of these cases the causative organisms were resistant to bacitracin. Some of the later preparations of bacitracin made by the deep tank method have shown evidence of nephrotoxicity. When the presently available bacitracin is used systemically, there should be repeated tests of renal function, and treatment should be discontinued if there is any indication of serious damage.

Results of Medical and Surgical Treatment of Essential Hypertension.—Davis and his associates present a classification of patients with essential hypertension and say that for surgical treatment they chose those with the high diastolic type of hypertension, and among these they selected those who had been given an adequate and thorough trial of therapy with the thiocyanates and had proven to be resistant to this drug. That is to say, their diastolic and systolic pressures and their symptoms could not be improved by cyanate blood levels below those which produced toxic symptoms. They found that sympathectomy alone has not been successful in permanently reducing the blood pressure levels in the high diastolic type of hypertension regardless of the extent of the operation. However, in some cases the subjective symptoms have been improved temporarily although the clinical course of the disease has remained unchanged. Sympathectomy has caused patients in this group who have been resistant to thiocyanate therapy preoperatively to become sensitive to the administration of this drug. This result has been confirmed by laboratory experiments on monkeys and dogs. There has been no significant change in the blood pressure levels, or heart size, unless the patients of this group have been given thiocyanates postoperatively. Vasopressor or vasorelaxor tests have not proved to be sufficiently accurate to determine exactly which of the patients with the high diastolic type of hypertension should be operated on. The medical management of patients of this group, particularly with the administration of thiocyanates properly controlled, is good in the early stages of the disease, but sooner or later all become resistant to this drug. The authors believe that those types of hypertension which respond well to medical management will show good results from surgical therapy alone, but the selection of patients for operation should be made, not on blood pressure ranges alone, but on the characteristic symptoms and clinical course of the disease. Until comparison of the results of surgical therapy is made on accepted classifications of the clinical symptoms and course of this disease, confusion in interpretation of the surgical results will exist.

Coarctation of the Aorta.—According to Bing and his co-workers, coarctation of the aorta belongs to the group of congenital cardiovascular malformations in which arteriovenous shunts are absent and in which there is no cyanosis. Diagnosis is not difficult if it is recalled that there is usually hypertension in the upper part of the body and hypotension below. The authors review observations on 23 patients who were operated on for coarctation of the aorta. Thirteen were 20 years of age or above, while 10 were younger. An anastomosis was completed in 21 cases of the 22 in which it was attempted. In 17 cases the stenosis was resected and an anastomosis of the proximal and distal ends of the aorta was performed. In 4 cases in which the proximal segment of the aorta was too short for end to end suture the left subclavian artery was used to by-pass the stenosis. There were 3 deaths. Physiologic investigations disclosed no significant deviation of the cardiac output from normal. Blood flows through the arm, which were elevated before operation, fell following surgery. Blood flow through the leg rose postoperatively. Hypertension in the upper part of the body and hypotension in the legs were observed preoperatively. After operation, these pressures tended to equalize. Analysis of the physiologic data indicated no generalized elevation of peripheral vascular resistance. It is probable, therefore, that the hypertension in coarctation of the aorta is not attributable to a renal pressor mechanism, but is due to the resistance of the stenosis and collaterals.

Low Backache with Persistent Muscle Spasm.—Price and her associates studied the patterns of muscular activity in acute and chronic back disorders and the effectiveness of treatment. Patients with acute and chronic pain in the back (resulting from simple muscular strain, joint irritation, arthritis or psychogenic disturbances) were studied through three methods: (1) localization of painful regions by repeated mappings of palpable painful foci; (2) removal of pain, either by treatment of the acute pain or by correction of abnormal patterns of activity; (3) analysis of movement by electromyographic recording of simple positions and movements. It was found that the areas of pain or tenderness migrate from one muscle group to another or from one part of a muscle group to another region of the same group. This shift of pain seems to be associated with the abnormal patterns of muscular activity developed in an attempt to avoid or relieve pain. Electromyographic studies during test movements gave evidence of the relative amounts of activity in various muscle groups in relation to pain as compared with normal subjects. Relief of the abnormal tensions in the muscles by correction of the abnormal patterns of activity may assist greatly in alleviating discomfort and preventing recurrences of pain.

Vitamin B_{12} in Tropical Sprue.—Spies and Suarez treated 5 patients with tropical sprue in Puerto Rico by injections of vitamin B_{12}. A single dose of 4 micrograms administered in 1 case produced little or no change. The larger dosage of 10 to 25 micrograms administered in other cases was accompanied by a striking increase in strength and vigor and a decrease in the diarrhea. In no instance was a maximum dose given, and these patients quickly tended to relapse clinically and hematologically. They could be relieved promptly again either by another injection of vitamin B_{12} or by a compound of folic acid. A single injection of approximately 100 micrograms of vitamin B_{12} would probably be needed to produce a full hematologic response. This tentative appraisal would suggest that vitamin B_{12}, per unit of weight, is more effective in treating human disease than any compound that yet has been used.

Gaucher's Disease in Adults.—Groen and Garrer report 9 patients, 4 women between the ages of 21 and 58, and 5 men between the ages of 25 and 47, with Gaucher's disease. Two of these patients were brother and sister, and three others constituted a family consisting of the father and 2 daughters. The patients presented most of the salient features of this rare, often familial disease which is distinguished by the presence of characteristic cells in the spleen, liver, lymph nodes and bone marrow. As a rule the patients do not have any complaints until relatively late, when the spleen and liver have already increased to a considerable size. During the "silent" stage the person is unaware of the condition. In 3 instances in this series the disease was discovered only when the relatives of a known patient were examined. The presence of the Gaucher cells does not necessarily upset the macroscopic structure of the bone; in the later stages the bones usually show generalized or local osteoporosis, but even in the cases of advanced disease the degree of macroscopic affection of the bone is variable, and consequently considerable variations in the clinical picture may be encountered. Repeated attacks of low backache radiating along the sciatic nerve were the first complaint in 2 patients. One patient entered the hospital with a spontaneous fracture of the shaft of the right femur; another presented "arthrosis" of the head of the femur, and bone abscess occurred in 2 patients. The diagnosis suspected on clinical grounds was definitely established by the detection of Gaucher cells in the smear of the sternal marrow. Puncture was carried out in the manubrium. One of the most important advantages of the sternal puncture is the possibility of establishing an early diagnosis in persons in whom the clinical picture is not fully developed. Sternal puncture has all the advantages of ease and safety and none of the drawbacks associated with the splenic or hepatic puncture in these patients with a known tendency to bleed.

Physiologic Aspects of Vagotomy.—Animal experiments carried out by Pavlov and his co-workers and by many other investigators demonstrated that complete vagotomy causes digestive disturbances severe enough to cause death of the animals. These disturbances comprise hypomotility of the stomach and hyposecretion of the stomach and pancreas and possibly the intestine, together with a peculiar hyperirritability of the intestine. These changes are interpreted by Thomas and Komarov as being mainly due to loss of tonic activity of the abdominal vagus. Evidence is reviewed which indicates that transthoracic or transabdominal vagotomy in experimental animals, and presumably in man also, is seldom complete, and it is suggested that the relative harmlessness of this operation as usually performed is due to this fact. Attempt to accomplish more nearly complete vagotomy in human subjects would probably be unwise:

Follow-Up of Vagotomy.—Moore performed vagus resection on 116 patients, 99 of whom had duodenal ulcer and 17 had jejunal ulcer. Follow-up study for a period of five to forty-five months showed that 13 of these patients (11 per cent) have had recurrence. Eight of these patients have had a frank recurrence of ulcer symptoms with the demonstration by roentgen ray of an ulcer crater or the occurrence of a demonstrable ulcer crater in the absence of symptoms. Five patients have had a recurrence of ulcer symptoms without a demonstrable ulcer crater. Of these 13 patients, all but 2 are now well without further treatment other than the simplest of dietary precautions. Abolition of gastric secretory response to insulin-induced hypoglycemia is not a lasting result of vagotomy; it has been observed to re-establish itself two to four years after vagotomy despite a long interval free of symptoms and free of secretory response to hypoglycemia. Resumed responsiveness may take the form of a "delayed" response. Vagus resection is not a cure for duodenal ulcer; it is a physiologic procedure which, by removing the majority of the parasympathetic nerves to the upper part of the gastrointestinal tract, renders the management of patients with duodenal ulcer a simple rather than a complicated problem. One case in a man aged 44 with duodenal ulcer is reported in which the right vagus fibers to the celiac ganglion were left intact but the left vagus entirely sectioned 3 inches (7.6 cm.) above the cardia and all fibers passing to the posterior wall of the stomach sectioned. Diarrhea was not lessened in this instance, although ulcer healing and abolition of the hypoglycemic reflex were produced.

Follow-Up of Gastric Vagotomy.—Dragstedt and Camp carried out section of a segment of the vagus nerves along the lower esophagus without additional gastric surgery on 144 patients, 133 men and 11 women, with intractable duodenal ulcers. In 56 of these the operation was performed by a transthoracic approach and in 88 by a laparotomy with incision of the diaphragm. One death occurred in the former group, but there have been no deaths in the latter series. These patients have been followed up for from one to five and a half years. Forty-five of the 56 patients (80 per cent), and 76 of the 88 patients (86 per cent) secured an excellent result from the operation with objective evidence of healing of the ulcer as determined by gastric fluoroscopy, complete absence of ulcer distress while on an entirely unrestricted diet and without any form of antacid medication, increase in body weight and return to the usual occupation, and with side effects trivial or inconsequential. The majority of the patients with an unsatisfactory result have been entirely relieved by subsequent gastroenterostomy for obstructive symptoms. Failure of the ulcers to heal or recurrence has usually been associated with incomplete vagotomy.

Contact Dermatitis from Topical Tyrothricin.—Goldman and his associates report the case of a woman, aged 43, in whom various treatments had failed to heal an ulcer on the ankle until compresses with solution of tyrothricin were applied. On later recurrence, the ulcer was again treated with solution of tyrothricin and began to heal, but after six weeks of treatment an acute eczematoid dermatitis of the lower leg developed. Penicillin ointment was then used without relief and with perhaps further aggravation of the dermatitis. There were no previous episodes of eczematoid dermatitis, no known fungous disease of the feet and, prior to the application of tyrothricin, no use of any antibiotic. There was also a moderately severe erythematous papulovesicular eruption of the upper extremities. Later the dermatitis subsided and patch tests were done with tyrothricin, penicillin, bacitracin and various other substances and a polyvalent hypersensitivity was detected. The authors are of the opinion that topically tyrothricin is less effective than penicillin or even streptomycin or bacitracin.

Sensitization to Antibiotic Agents. — Berke and Obermayer subjected 51 nurses, who had previously handled streptomycin, to patch tests with streptomycin, penicillin, tyrothricin and procaine hydrochloride. Each subject was questioned concerning recent eczematous eruptions, her length of service in the chest or urologic division and the frequency of handling streptomycin. All 51 nurses had administered penicillin, the majority had had some contact with procaine hydrochloride and a smaller number had administered tyrothricin, which is used as a topical application. Twenty of the 51 nurses gave positive evidence of hypersensitivity to streptomycin, 20 to procaine hydrochloride, 13 to penicillin and 2 to tyrothricin. Fourteen of the 20 who reacted to streptomycin also reacted to procaine hydrochloride and/or penicillin; 13 of this group had a history of previous eczematous dermatitis. It is evident that streptomycin is an important contact type sensitizing agent, but procaine hydrochloride when used concomitantly with streptomycin seems to be significant in the causation of eczematous dermatitis.

Antigenic Differences Among Influenza A Viruses.—Morgan and his co-workers tested for virus the throat washings of 13 patients during the epidemic of influenza which occurred in Boston in March and April 1947. Strains of influenza were isolated from the throat washings of the 13 patients and a strain also was obtained from the nasal secretions of one of them. These strains were shown to be antigenically distinct from several classic strains of influenza A and from strains of influenza virus isolated in Boston during and shortly after the 1943-1944 epidemic. The strains from both epidemics, however, showed some antigenic relationship to the PR8 strain of influenza A, but not to the Lee strain of influenza B. Evidence was presented which suggested that at least two antigenically distinct strains of influenza virus were active during the 1947 epidemic; one of them closely resembled the FM_1 strain isolated elsewhere during the same season. Antigenic differences were also demonstrated among strains of influenza A isolated in Boston during and after the outbreak of 1943-1944. During the 1947 outbreak, higher titers and greater rises in titer of influenza antibodies were elicited in the serums of patients with the PR8 strain than with the epidemic strains. A strain of virus isolated from a sporadic case of clinical influenza in December 1947 showed no antigenic relationship to any of the influenza viruses included in this study. Antibodies against this strain could not be demonstrated in the serum of the patient from whom it was isolated.

Hepatic Dysfunction in Infectious Mononucleosis.—Peterson studied 40 patients with typical infectious mononucleosis, 21 of whom showed moderate to severe hepatic functional involvement or hepatitis as evidenced by a battery of hepatic function tests. A few of the remaining 19 patients exhibited milder hepatic involvement on the basis of positive reactions to one or two positive tests. It has not been feasible to differentiate the type of hepatic involvement in these patients with infectious mononucleosis and hepatic dysfunction from that in cases of acute epidemic or sporadic hepatitis. One must rely on the clinical picture, especially the presence of pharyngitis, the type of lymphocytic reaction and the titer of the heterophile antibodies. The character of the disturbances in hepatic function in these patients points to the presence of both hepatocellular and cholangiolar liver injury. This evidence, together with the microscopic observations reported in the literature, tends to refute the concept that jaundice in infectious mononucleosis is due to an extrahepatic obstruction of the common bile duct by enlarged lymph nodes.

Antireticular Cytotoxic Serum in Arthritis.—Kling administered antireticular cytotoxic serum to 60 patients with chronic rheumatic disease, 30 of whom had rheumatoid arthritis, 20 had osteoarthritis and 10 had fibrositis. Two schedules were used. One, according to the original directions of Bogomolets, consisted of an injection of 0.5 cc. of antireticular cytotoxic serum followed after an interval of two or three days by 0.1 cc. and concluded with 0.15 cc. after the same interval. The second method of administration employed was that by Strauss and his associates, with injections given twice weekly starting with 0.02 cc. of the serum. The dosage was increased by 0.02 cc. at each subsequent injection to a maximum of 0.2 or 0.25 cc. This dose was repeated up to six weeks, depending on the response of the patient. Injections were given subcutaneously. With both methods the series can be given several times after an interval of at least four weeks. From the results obtained and from a review of the literature it is concluded that there is no indication for antireticular cytotoxic serum in the treatment of osteoarthritis and fibrositis, which are ameliorated as a rule by physical, orthopedic and drug treatment. In rheumatoid arthritis and Strümpell-Marie spondylitis, which are often resistant to treatment, a trial of antireticular cytotoxic serum, on the basis of an occasional significant improvement as in 1 of the authors' cases, may be justified. Important objections to Bogomolets' concept of the extended reticuloendothelial system are as follows: It is not proved that the reticuloendothelial system is depressed in any type of rheumatic disease; the role of the reticuloendothelial system in pathogenesis and treatment has not been definitely established; in the rheumatic disease presented in the author's material and reviewed from the literature the results of antireticular cytotoxic serum have been discouraging. It is doubtful that antireticular cytotoxic serum is a true antireticular serum. Its introduction into general practice, especially in the therapy of rheumatic diseases, should not be encouraged.

Mesoblastic Nephroma in Adults.—Culp and Hartman point out that embryonal tumors of the renal cortex have been reported with more than fifty different pathologic diagnoses. The result is great confusion in nomenclature. After reviewing the literature and after careful histologic study of 8 of their own cases of embryonal cortical kidney tumor, the authors are convinced that all of these embryonal neoplasms are closely related rather than distinct morphologic entities. They suggest that these tumors be called mesoblastic nephromas and that more complicated pathologic terms, as well as the name "Wilms' tumor," be avoided. Most cellular variations can be included in the mixed, carcinomatous and sarcomatous groups. Further differentiation has no virtue and adds to the current chaotic state of terminology. These embryonal tumors occur at any age, in both sexes, in either kidney, usually are very malignant, tend to recur after either lumbar or transperitoneal nephrectomy, mestastasize to lymph nodes, lungs and liver most frequently, cannot be distinguished from other renal neoplasms clinically and appear to be influenced little by irradiation. The clinical course usually is rapid, and most deaths occur within twelve months of diagnosis and treatment regardless of the specific type of tumor. Like other malignant tumors, surgical cures will depend on early recognition, and even then survival will probably be confined to the few mesoblastic nephromas with relatively low grade malignancy.

Necroptic Studies in Carcinoma of Prostate.—Arnheim presents an analysis of the protocols of postmortem examinations of 176 cases in which carcinoma of the prostate was found. The material was drawn from 21,718 postmortem examinations. No case was found in a person younger than 42 years. Of the total of 176 patients, 139 died of carcinoma of the prostate and 37 died of other causes. There was a sudden increase in incidence of carcinoma of the prostate at the age of 60, regardless of whether the patient died of it or whether the carcinoma was an incidental finding. Ninety-six per cent of the carcinomas were adenocarcinomas. Metastases were not discovered in 33 per cent of the cases. One third of all the metastases were visceral. Bone and lymph node involvement constituted 66 per cent of all metastases. Periaortic, iliac and tracheobronchial lymph nodes were involved in the order mentioned. The bladder was most commonly involved by direct extension. Carcinoma of the prostate is biologically active in some patients and inactive in others.

Streptomycin in Genitourinary Infections.—Satterthwaite and White say that among the 200 patients with paraplegia admitted to their hospital there were many with renal and ureteral calculi. In addition, there were many battle casualties who had formed multiple stones of recumbency. In some of these patients severe pyelonephritis developed. Often the patients were in too poor a condition for a major operation. The success of streptomycin in eliminating fever and toxicity and confining the infection to minimal limits, especially in patients with Escherichia coli infections, permitted the authors to remove urinary calculi by elective rather than emergency procedures. The results of therapy in the 51 cases in which treatment was with streptomycin are presented. Streptomycin was beneficial in 14 of 15 cases of acute severe pyelonephritis which had developed after acute ureteral obstruction. Of 8 cases of urinary sinus tracts treated with streptomycin, complete healing was obtained in 6. Moderate improvement was obtained in the other 2 cases. Two of 3 patients with chronic interstitial cystitis showed improvement. Total arrest of symptoms was obtained in 3 patients with resistant gonococcic urethritis. Five patients with tuberculosis of the genitourinary tract were treated; 4 of these had tuberculous cystitis. Each of these 4 patients had remission of symptoms and healing of the vesical lesions. No improvement was observed in tuberculosis of the seminal tract. The dosage of streptomycin has usually been 1 or 1.5 Gm. a day. Except for the tuberculous infections, the effectiveness of the streptomycin is usually manifested by the fifth day. The authors have been disturbed by the serious toxic reactions, which included 5 cases of involvement of the eighth nerve, one lasting four months. In 2 cases impairment of auditory acuity developed as a delayed reaction. There was 1 case of mild neutropenia. One case of thrombopenic purpura was observed. It is believed that much greater caution is necessary in streptomycin therapy than with penicillin or sulfadiazine therapy.

Hepatic Coma.—Murphy and his co-workers report clinical and laboratory studies on 40 patients with severe primary hepatic disease who died in coma. Liver coma is a distinct clinical syndrome characterized by a progression from lethargy to noisy confusion, to coma and usually to death. The syndrome occurs in patients with severe hepatic disease, either spontaneously or as the result of infection, hemorrhage or sedation. In half the patients, the coma was precipitated by infection (17 patients), acute hemorrhage (2 patients) or cerebral metastases (1 patient). Central nervous system depressants have a prolonged action in patients with hepatic disease and in this way are believed to play an important role in the genesis of liver coma. Aside from evidence of severe hepatic disease, the physical examination and laboratory findings during coma are not distinctive nor are they significantly different from precoma findings. Treatment, which is generally unsatisfactory, is directed at maintenance of nutrition, control of infection or hemorrhage and avoidance of sedatives. Analeptics, including glucose, sodium succinate, caffeine and amphetamine, are without effect on the comatose state.

Intussusception in Childhood.—Gross and Ware report 610 children, 397 boys and 213 girls between the ages of 3 days and 12 years, with intussusception. The peak of incidence with 415 cases occurred between the third and the eleventh month of life. The causation in 95 per cent of the cases was not known. Intussusception is characterized by sudden onset of paroxysmal abdominal pain, vomiting, bloody stools and a palpable abdominal mass, the condition occurring usually in a well nourished infant. Roentgenologic examination by barium enema may be an aid in the diagnosis of atypical cases, but it is not required in the majority of cases in which the history and physical findings are sufficient to establish the proper diagnosis. Surgical reduction of the intussusception after rapid but important preoperative preparation is the treatment of choice. If resection is necessary, exteriorization is the preferred method, since this prevents contamination of the peritoneal cavity. Postoperative care includes the use of gastric suction, transfusion of blood or plasma, infusion of dextrose or isotonic solution of sodium chloride and in some cases institution of chemotherapy and placement of the child in a high-concentration oxygen tent. The mortality has been reduced to 2.7 per cent.

Neurophysiologic Disturbances Following Electric Shock Therapy. — Weil summarizes electroencephalographic studies on 150 patients who were subjected to from three to twenty electroshock treatments for various psychiatric disorders. Many of the abnormal wave patterns observed resembled epileptic patterns. The incidence of abnormalities seemed to be somewhat less frequent when unidirectional current was used (Reiter apparatus) than when alternating current was used. More than ten shock treatments produced generally longer-lasting and more pronounced brain wave abnormalities. The youngest and the oldest age groups show the most pronounced electroencephalographic abnormalities after shock treatment. It appears also, that a normal preshock electroencephalogram promises a better clinical result from electroshock therapy than an abnormal one. It is suggested that whenever possible electroencephalographic studies should precede electroshock therapy. Psychotherapy should be substituted for electroshock treatment at least after ten treatments.

Cystic Fibrosis of Pancreas. — Sinclair reports a male infant who was hospitalized when 9 weeks old and who died at 5 months. The case is significant because it calls attention to the fact that the clinical and pathologic aspects of cystic fibrosis of the pancreas may be present even though the enzyme activity of the duodenal juice and the total fat content of the stools are normal. This unusual circumstance is explained in this instance by the microscopic observation that approximately one half of the pancreas was the seat of cystic fibrosis while the remainder was practically normal.

Reproductive Histories of Mothers of Infants with Erythroblastosis.—In connection with studies of erythroblastosis fetalis conducted at the Chicago Lying-in Hospital between 1935 and 1947, inclusive, reproductive histories have been obtained for 175 Rh-negative women who have given birth to one or more infants proved to have had this disease. Potter says that these women had a total of 669 pregnancies during the period under investigation. They had 341 pregnancies preceding the birth of the first infant with erythroblastosis. These resulted in 7 stillbirths, 13 neonatal deaths, 65 abortions and 256 surviving children. Forty-four of these abortions followed the birth of the last normal child and preceded the birth of the first child with erythroblastosis. The average number of surviving children born to each patient before the birth of an infant with erythroblastosis was 1.4. The diagnosis of erythroblastosis was made for the first time in 7 women in a first pregnancy and 168 women in second or subsequent pregnancies. Four of the women without earlier pregnancies had had trans-
f
Of the 178 infants affected, 56 died before birth, 60
birth and 62 survived. Ninety-six women had 179
following the birth of an infant with erythroblastosis. These have ended in the birth of 3 Rh-negative, 144 Rh-positive infants with erythroblastosis and 32 abortions. Thirteen of the abortions are known to have been induced. Sixty-nine of the Rh-positive infants were stillborn, 63 died and only 12 survived. Three of the latter are known to have brain damage. Among 18,468 deliveries the frequency with which erythroblastosis occurred for the first time varied from once in 2,814 deliveries for women in their first pregnancies to 1 in 172 in second pregnancies and in 1 in 55 for sixth pregnancies. In the last two years no liveborn infant has died of erythroblastosis in the Chicago Lying-in Hospital who had not had an older sibling affected by the same disease. In evaluating treatment, the previous reproductive histories of the mothers of the treated infants must be taken into account. In the experience of the author the previous maternal history has been of more value in prognosticating the fate of an infant born to an immunized Rh-negative woman than have changes in maternal antibody titer or differences in the variety of antibodies present.

Fibrocystic Disease of Pancreas and Deficiency of Secretin.—Baggenstoss and his associates say that in recent histopathologic studies of the pancreas the occurrence of a remarkable degree of dilatation of the acini, flattening of the lining epithelial cells and inspissation of secretion has been described in a variety of pathologic states. The histologic appearance of the lesion is similar to that observed in the early stages of fibrocystic disease of the pancreas in children. The lesion has occurred with a high incidence in persons dying of uremia, carcinoma of the stomach, obstruction of the small intestine, chronic ulcerative colitis and sepsis. On the basis of analysis of the cases and a review of pertinent experimental work, it was concluded that in the pathogenesis of this lesion there is inhibition of the type of pancreatic secretion normally stimulated by secretin. There is also nervous stimulation of the pancreas, leading to depletion of zymogen granules and formation of a thick, viscid juice. There is dehydration which results in inspissation of the juice and the development of intrinsic obstruction. Finally, there is malnutrition (deficiency of protein), resulting in failure of reparative protein synthesis in the cells of the pancreatic acini. It was postulated that a congenital deficiency of secretin is responsible for fibrocystic disease of the pancreas in children. The authors are of the opinion that the varied clinical and pathologic manifestations of this disease can be more nearly adequately explained by this hypothesis than by any of the other current theories. The absence of secretin in the upper part of the intestinal tract of a patient with fibrocystic disease of the pancreas lends support to this theory. It has been shown to be possible to extract secretin from the upper part of the intestinal tract of persons 2 months to 73 years old. Consistent failures occurred in work with patients in the neonatal period. Successful extraction of secretin from these patients in the neonatal period can be carried out, however, by combining the crude extracts obtained from a number of patients. The extraction of secretin is successful if it is done up to fifteen hours post mortem. Because this method of extraction is successful in individual cases at necropsy, it becomes possible to correlate the presence or absence of secretin with varying pathologic conditions.

Accidents in Spinal Anesthesia.—Recent reports in medical literature have emphasized procaine sensitivity as a possible cause of reactions after spinal anesthesia and have advised the testing of sensitivity by dermal tests. De Guzman and Quitco believe that dehydration is a factor in some of these accidents. The 2 reported cases, in which spinal anesthesia was followed by severe complications, concerned patients who had not taken adequate amounts of fluid before the induction of spinal anesthesia and who were in a state of relative dehydration, which involves low blood and cerebrospinal fluid pressures. A low spinal fluid pressure signifies less spinal fluid to mix with the anesthetic agent and therefore a greater procaine concentration. Dehydration of the body secondary to the preoperative fasting or to acute pathologic conditions would seem to contraindicate spinal anesthesia unless fluids required by the body are supplied. Patients should take plenty of fluids the day and night before and on the day of operation. Artificial respiration is important when an accident results from spinal anesthesia. Venous fluids should be on hand. Although epinephrine is effective in raising the blood pressure in spinal anesthetic shock, caution should be used in giving it. In case a high intercostal paralysis results from the anesthetic, the best position for the patient is a flat horizontal one. It is better to give artificial respiration before injections.

Role of Pleura in Pneumonectomy.—Tchertkoff and Selikoff report 77 patients with pulmonary tuberculosis on whom pneumonectomy was performed at Sea View Hospital during the period March 1946 to April 1948. In 52 of these, intrapleural pneumonectomy was done, all or large portions of the parietal pleura being left intact. In the remaining 25 patients the operation was extrapleural and either all or nearly all of the parietal pleura was removed. Intrapleural pneumonectomy was followed by bronchopleural fistula and/or empyema in 19 patients, results similar to those reported by other workers. Besides these serious complications, 8 patients had wound difficulties, 5 suffered spread and 2 were failures. In contrast to this no case of empyema was observed in the entire group in which extrapleural pneumonectomy was performed; there were no deaths, no spreads and no failures. It is suggested that this difference in results is due to the total removal of the parietal pleura in extrapleural pneumonectomy. In contrast the retention of the parietal pleura during intrapleural pneumonectomy leaves a source of serious postoperative complications. The future treatment of postresectional reopening of the bronchial stump may be early extensive pleurectomy rather than bronchoplasty and/or thoracoplasty as currently employed.

Streptomycin in Tuberculous Meningitis.—Wainerdi and Worthen treated a woman aged 21 who had tuberculous meningitis with 257.2 Gm. of streptomycin given in sixty-seven intrathecal instillations of 200 mg. (200,000 units) each and six hundred and twelve intramuscular injections of 400 mg. (400,000 units) over a period of one hundred and fifteen days. The positive observations on admission were limited to nuchal rigidity and general hyperirritability. The patient's complaints at this time were limited to excruciating headache which seemed to be occipital and an inconstant diplopia. The patient was followed by careful examination preceding each lumbar puncture, of which 80 were performed, either for medication or diagnostic purpose, during her course. She had a three day period of extreme excitement early in her course. Seven weeks after admission the patient had begun to show definite clinical improvement and could touch her chin to her chest without pain. Her diplopia had all but vanished. During the eighth week tinnitus, which had for several days been transitory, set in again, and five days later she began to complain of deafness. It was about this time that the first course of punctures was interrupted in order that the element of chemical—i. e., streptomycin—arachnoiditis might be evaluated. The patient was followed by diagnostic punctures every four days. Her condition worsened and she had an episode which mimicked her original syndrome. At this time a second course of intrathecal instillations was begun. At her discharge to a rigidly supervised home regimen the patient had definite clinical improvement in all spheres but the auditory. She is being followed at home with frequent lumbar puncture accompanied by extensive physical and neurologic examination. The authors believe it conservative to state that the patient's meningitis of established tuberculous origin has been cured. There were clinical and laboratory reasons for concluding that a toxic (chemical) meningitis developed from the drug which was used. She continues to have a residium in the form of severe eighth nerve deafness bilaterally.

Pathology of Pulmonary Fibrosis.—According to Mallory proliferation of fibroblasts resulting in the development of abnormal fibrous tissue in the lung is a common sequel of many types of injury to the pulmonary parenchyma. Few lungs of adults are found free from foci of fibrosis at necropsy. The term "pulmonary fibrosis," however, is rarely used as a diagnosis when the causation of the fibrous reaction is obvious, as in fibroid phthisis, lipid pneumonia or silicosis, nor is it commonly applied to localized scars such as healed infarcts, but is reserved for examples of multifocal or generalized involvement of the lungs, the origin of which is dubious or unknown. It is the pathology of this latter group which is the subject of the present paper. Four types are described: (1) organized pneumonia, (2) healed infarction, (3) healed necrotizing pneumonitis and (4) interstitial fibrosis. In a survey of 6,000 necropsies, 59 cases of pulmonary fibrosis (exclusive of tuberculosis, silicosis and lipid pneumonia) were recorded. Of these, 23 were judged to be clinically significant. Among this number, three groups were considered of interest. It is pointed out that the incidence of organized pneumonia in patients with chronic bronchial asthma is too high to be coincidence, that in radiation pneumonitis the picture is frequently complicated by the scars of necrotizing pneumonitis and of healed neoplasia. A progressive form of granulomatous pneumonitis healing by fibrosis is described, and evidence is presented for considering this a form of localized pulmonary sarcoidosis.

Cancer of Larynx.—The report by Cutler is based on a study of 107 consecutive, microscopically proved cancers of the larynx treated by radiation in the Chicago Tumor Institute. The author discusses concentration radiotherapy, a term which he introduced to emphasize two factors: the administration of a large total dose in a relatively short period (eighteen days) and the use of an increasing dose through a diminishing portal. Criteria for selection of treatment are discussed. Five year cures were obtained in 37 patients (35 per cent). More than half the cases were inoperable. Among the operable cases beyond the scope of laryngofissure the only surgical alternative for which was total laryngectomy, radiotherapy effected 52 per cent five year cures, and among the inoperable group, 20 per cent of the patients are free of disease after five years. The five year curability among the cases in which the cords were not completely fixed is 60 per cent. The author believes that when the cords are freely movable or only partly fixed by carcinoma, curability is high (60 per cent) and radiotherapy is the method of choice. Laryngectomy is indicated for intrinsic lesions with complete fixation of the cords occurring in subjects of good life expectancy, provided the fixation is caused by carcinomatous invasion and not by inflammation. If, after careful consideration of all factors, a decision between radiotherapy and laryngectomy remains difficult, a radiotherapeutic test or complete irradiation should be considered as the initial procedure. There is reason to expect that further improvements in the technic of irradiation and earlier diagnosis will further diminish the necessity for total laryngectomy.

Radioactive Iodine in Thyroid Disorders.—Werner and his co-workers show that since the release of isotopes from the pile at Oak Ridge it has been possible for suitably equipped institutions to obtain radioactive iodine (I^{131}). Accordingly an appraisal of the treatment of toxic goiter with this agent has been undertaken in several hospitals, and this paper is a preliminary report of observations made until now. Radioactive iodine of eight day half-life (I^{131}) has been used as a tracer and for treatment of toxic goiter. Tracer uptake has diagnostic value when stable iodine has not been given shortly before this procedure and when the diet has not been seriously deficient in iodine. Normal uptake is 15 to 30 per cent of the administered tracer dose of 40 to 100 microcuries. Anything more than 40 per cent is regarded as definitely indicating hyperthyroidism; anything less than 10 per cent as hypothyroidism. Therapy has been successful in 30 of 34 cases after one or, when necessary, two doses, with 4 failures. Six other cases did not respond to one dose, and have not been followed after a second long enough to draw conclusions. Failure appears to be related to inadequate dosage, as a result mainly of large size of the gland. An unusually high basal metabolic rate may also contribute to an unsatisfactory result. Complications following radioiodine therapy include sore throat, cough, tender gland, flare-up of toxicity and transient hypothyroidism. Only a few cases of each have been observed, none of them serious. Malignant change in later years following treatment with radioiodine is not thought probable. Radiation hazards to doctors and others associated with patients undergoing this therapy are analyzed; under the present conditions they are unimportant.

Human Bites.—To the approximately 800 cases of human bites already on record in the literature, including 90 previously reported from Charity Hospital of Louisiana at New Orleans, Boyce adds a second series of 126 bites in 93 patients. Of the 126 bites, 79 affected the hand. Bites on parts of the body other than the hand are regarded as less dangerous than bites on the hand, and, generally speaking, this is correct. However, patients with bites on the nose, lips, cheeks and chin have suffered severe infections. The serious consequences of human bites are believed the result of a combined infection in which the fusiform bacillus and the spirochete, in symbiosis, play the chief role but in which other organisms are also concerned. A human bite sustained by a blow of the fist against the teeth may damage an extensor tendon, sometimes completely severing it, may fracture a metacarpal bone and may directly penetrate a joint capsule. When the hand is extended after the injury, the injured surfaces are buried under overlying tissue. The result is a state of devitalization and anaerobiosis in which the fusiform bacillus and the spirochete thrive. Furthermore, the organisms of the human mouth are already acclimated to growth in human tissues and fluids, and therefore are already thriving before the defenses of the host can be mustered against them. The ideal treatment of a human bite seen early (within three or four hours of injury) includes: (1) cleansing for at least ten minutes with soap and water, followed by thorough irrigation of the wound with isotonic sodium chloride solution or clear sterile water; (2) determination of the depth and character of the injury by gentle retraction of the wound edges; (3) splinting of the hand with massive dressings in the position of function, followed by the application of moist heat, if no surgical treatment is indicated; (4) excision of devitalized tissue; debridement should be thorough but also conservative; (5) hospitalization for at least forty-eight hours, or as much longer as is necessary to determine that infection will not occur, and (6) the administration of both sulfathiazole (or sulfadiazine) and penicillin. The management of a patient seen late should follow the general principles of cleansing, examination, splinting and postoperative treatment which have been outlined. Primary wound closure is definitely contraindicated in human bites.

Multiple Primary, Self-Healing Squamous Epithelioma of Skin. J. F. Smith.—p. 315.
*Sunlight and Skin Cancer in Kenya. F. Piers.—p. 319.

Sunlight and Skin Cancer in Kenya.—According to Piers the concept that frequent and prolonged exposure to sunlight may lead to the development of cutaneous cancer in man has received considerable support by recent experimental and epidemiologic work. Since 1941 he has seen 51 cutaneous cancers in the white population of Kenya Colony, where cutaneous cancer is second in frequency only to breast cancer. Most of the patients with cancer gave a history of frequent and prolonged exposure to the sunlight of equatorial Africa. The severe types of chronic sunburn described under the names of farmer's skin and chronic solar dermatitis were present in two thirds of the patients with cancer. The conclusion seems to be justified that sunlight is the paramount factor in the causation of cutaneous carcinoma in Kenya. The farmer, rancher and white hunter are exposed to the equatorial sun by necessity; but the town dweller, following the command of fashion, exposes himself voluntarily with a truly alarming recklessness. The habit of dispensing with the Victorian sun helmet altogether and of participating in outdoor activities and sports without adequate protection is widespread among the younger generation of Kenya.

Hernia and Prolapse of Vitreous and Prolapse of Iris in Connection with Cataract Operation. M. Vannas.—p. 776.

Keratitis Rosacea.—Walker points out that keratitis rosacea, a relatively common abnormality of the skin of the face of adults between the ages of 20 and 50 years, is frequently accompanied by ocular manifestations, varying in degree from mild conjunctivitis, through all the stages of blepharoconjunctivitis, episcleritis and keratitis, to eventual visual incapacity. Analyzing 76 cases of keratitis rosacea, the author found that in 52 an allergy was the cause of both the skin and the corneal lesions. After desensitization, 70 per cent of patients remained symptom free for at least two years.

Migraine.—Walker analyzed 100 patients with migraine and found that in 54 of them the migraine was of allergic origin. They remained free from attacks after desensitization or avoidance of their allergens. The author also noted that the average systolic blood pressure of the 54 allergic patients was noticeably lower than that of 46 nonallergic ones.

Folic Acid in Nontropical Sprue.—Ferguson and Calder attempted to assess the effect of synthetic folic acid in nontropical sprue, particularly with regard to the effect on intestinal function as judged by fat absorption and by roentgenologic appearances of the small intestine. They review results obtained in 7 patients. The three youngest, aged 15, 17 and 18, gave a definite history of celiac disease in childhood and had had previous hospital treatment. Two, aged 31 and 48 years, had a history suggestive of defective fat absorption in earlier life, while in the remaining 2 patients, aged 32 and 35, no such history could be elicited and the symptoms were of relatively short duration. Prior to therapy, the patients were kept under observation for two weeks during which they were subjected to various tests. The folic acid was usually given in doses of 20 mg. or 10 mg. daily for periods of two, three or six weeks. Among the patients in whom the bone marrow was normoblastic only 1 appeared to obtain subjective improvement. In the others, the general condition was unaltered or had deteriorated. There was no evidence of improvement in fat absorption, biochemical findings, blood picture or intestinal pattern in any of the patients. Of the 2 patients who were known to have had megaloblastic marrow reaction, one showed clinical and hematologic improvement and a return of the intestinal pattern to normal, but the steatorrhea persisted. In the other there was no apparent clinical or hematologic improvement, but again there was a striking roentgenologic improvement without improvement in fat absorption.

p-Aminosalicylic Acid: Determination in Blood and Cerebrospinal Fluid. W. Klyne and J. P. Newhouse.—p. 611.

Streptomycin Therapy of Tuberculous Meningitis.—Choremis and his associates say that from April to November of 1947 a total of 72 patients with tuberculous meningitis were treated at the University of Athens. All 9 patients who did not receive streptomycin died, whereas of the 63 patients who received combined intramuscular and intrathecal therapy 29 survived. The earlier the treatment the more favorable the prognosis. By "early" is meant within the first ten days from the onset. Dosage depends on the time when treatment is begun in relation to the stage of the disease, and to a less extent on the patient's age. Very young children usually need and tolerate streptomycin in larger doses per unit of body weight than do older ones. Tuberculous meningitis combined with miliary tuberculosis needs larger doses and longer treatment than meningitis alone. The best results have been obtained with intermittent treatment with intervals of rest. The authors believe that paratracheal adenitis in primary tuberculosis is too often a forerunner of tuberculous meningitis for this to be regarded as coincidental, and they consider that streptomycin should be used in the treatment of severe cases of primary tuberculosis in children. Of 18 such patients 12 subsequently contracted tuberculous meningitis. Intrathecally administered streptomycin is essential in tuberculous meningitis, but the intrathecal dosage should be kept to the effective minimum. The effect of the drug must be watched all the time.

Carinamide and Concentration of Penicillin in Blood.—The experiments described by Hunter and Wilson were designed to determine the effect of carinamide on the blood penicillin levels which can be achieved by repeated three-hourly or four-hourly injections, by a single injection, and by penicillin given by mouth. The patients were men between the ages of 20 and 52 who were convalescing from acute infections; none had evidence of renal impairment. The authors say that their findings are in agreement with the recent American work. They show that carinamide can be given by mouth *in doses sufficient to delay the excretion of penicillin* and to raise the blood-penicillin levels. Systemic toxicity is apparently low. There is no evidence of damage to the kidney, and the tubular inhibition is readily reversed by stopping the administration of carinamide. Unfortunately in the case of many preparations several years may elapse before these are clearly recognized. For this reason a drug which interferes with tubular function should be used with caution. *This is* especially the case with carinamide because of the appearance in the urine of a reducing substance which is apparently a pentose and may well be a product of disorganized cellular metabolism. For these reasons the authors suggest that until carinamide has had a more extensive clinical trial its use should be restricted to those cases in which the maintenance of high blood-penicillin levels is essential.

Denervation in Carotid Sinus Syndrome.—Turner and Learmonth report the case of a man, aged 61, who had benign essential hypertension and frequent incapacitating attacks of giddiness, which were shown to be due to hypersensitive carotid sinus reflexes. Bilateral carotid sinus denervation was carried out, and during the succeeding year the patient has been free from attacks. There were no adverse effects from the operation.

Fatal Enteritis During Streptomycin Therapy.—Kramer presents a fatal case of enteritis in an infant receiving streptomycin by mouth. A streptomycin-resistant coagulase-positive Staphylococcus aureus was obtained in pure culture from the terminal ileum at necropsy. It is suggested that the Staph. aureus, already present elsewhere in the body, was rendered resistant to streptomycin by the small amount of the drug absorbed from the intestine and that elimination of the normal intestinal flora may have contributed to the establishment of the Staph. aureus there.

*Rheumatoid Arthritis After Injury to Single Joint. M. Kelly.—p. 309.
Congenital Cystic Disease of Lung. K. M. Bowden.—p. 311.

Rheumatoid Arthritis After Injury to Single Joint.—Kelly reports 10 cases in which there was no rheumatic history before the precipitation of chronic polyarthritis by injury to a single joint. When rheumatoid arthritis follows injury to a joint the spread of the disease shows a striking preference for symmetric patterns. The constitutional pattern that favors the spread of the disease seems to be a transient rather than a permanent condition of the organism.

*Factors Influencing Plasma Concentrations of Salicylate. W. A. Parker.—p. 229.
Hemochromatosis. Observations on Incidence and on Value of Liver Biopsy in Diagnosis. W. E. King and E. Downie.—p. 247.

Toxic Effects of Calciferol.—The investigation reported by Anning and his associates involves 200 outpatients, the greatest majority (167) of whom had lupus vulgaris. The others had sarcoidosis, Bazin's disease (tuberculosis indurativa), tuberculosis verrucosa cutis, scrofuloderma, tuberculous lymphadenitis and similar disorders. All patients received 2 pints of milk daily in addition to their normal rations. Calciferol was given daily by mouth in tablet form in doses varying between 50,000 and 150,000 international units. The period of treatment varied between one and twenty-one months. Apart from clinical, and in some cases radiologic and electrocardiographic, examinations, biochemical investigations were undertaken. Total serum calcium determinations were made. The diffusible calcium was determined by an ultrafiltration technic and the serum protein determination by a copper sulfate technic. The ionic calcium and the inorganic phosphorus were also estimated and the renal function was examined in some of the cases. In 38 of the 200 patients toxic symptoms developed as the result of treatment with calciferol. The authors gained the impression that calciferol given in a daily dosage of 100,000 to 150,000 international units or in a dosage of more than 1,100 international units per kilogram of body weight may cause toxic symptoms or biochemical changes indicative of toxicity. The diagnosis of toxicity may be made by consideration of the symptoms and biochemical changes, of which a rise in the diffusible serum calcium is the most reliable. A rise above 7.5 mg. per hundred cubic centimeters of serum calcium appears to indicate the presence of toxicity. The effects of calciferol intoxication fall most heavily on the kidneys. Impairment of function may be temporary or may persist and may be present without symptoms of toxicity.

Plasma Concentrations of Salicylate.—Parker aimed to determine the influence of dosage, frequency of administration, route of administration, fluid intake and precipitation and deterioration of mixtures of sodium salicylate and sodium bicarbonate on plasma concentrations of salicylate. Excretion was studied over many days. The majority of patients on whom observations were made were receiving sodium salicylate during the treatment of rheumatic fever and rheumatoid arthritis, and the remainder were convalescent. The authors found that although maximal plasma concentrations occurred two hours after oral administration, four-hourly dosage maintained plasma levels successfully. A low fluid intake increased plasma concentration of salicylate when a fixed daily dose of sodium salicylate was continued. After such a rise the resumption of adequate fluid intake speedily diminished plasma concentrations. There was a reduction of 10 per cent in salicylate content of mixtures of sodium salicylate and sodium bicarbonate after standing for three weeks. Inadequate shaking of such mixtures before administration caused the salicylate content of a dose to vary from 70 to 120 per cent of the expected amount. Maximal plasma concentrations followed eight hours after administration of sodium salicylate, but the addition of alkali diminished absorption of the drug from the rectum. Satisfactory plasma levels and therapeutic response was shown in 2 cases of rheumatic fever treated by the rectal route throughout the illness. Plasma concentrations obtained by oral and intravenous administration of sodium salicylate were compared, and no advantage was found in the intravenous administration. Urinary excretion was correlated with plasma concentrations of salicylate and with concurrent administration of sodium bicarbonate, potassium citrate, ammonium chloride and para-aminobenzoic acid, after it had been shown that no salicylate was excreted in the sweat and only negligible quantities in the feces. It was shown that alkaline salts diminished plasma salicylate concentration by 10 to 35 per cent by causing an increased excretion of free salicylate in the urine, while ammonium chloride and para-aminobenzoic acid had the opposite effect. There was a direct relationship between increased excretion of free salicylate and the p_H of the urine.

*Folic Acid: Report of 12 Patients Treated with Synthetic Pteroylglutamic Acid with Comments on Pertinent Literature. L. Berk, J. L. Bauer and W. B. Castle.—p. 604.
Secondary Infection in Chronic Amebic Colitis: Clinicopathologic and Radiologic Study. A. M. Beemer, E. Samuel and A. Shedrow.—p. 612.
Two Separate Uteri: Case Report. H. F. Lowenthal.—p. 626.

Treatment with Folic Acid.—Berk and his co-workers review observations on 12 patients with pernicious anemia who were treated with synthetic pteroylglutamic acid (folic acid). The dosage was 10 mg. intramuscularly daily during the initial stages of the response, during which time the patients were given a diet containing no meat, fish, eggs or other recognized hemopoietically active substances. This was followed by maintenance with 75 mg. intramuscularly once a week during which no dietary restrictions were imposed. The reticulocyte responses and initial rises in red cell count and hemoglobin were comparable to those seen with purified liver extract therapy. Neurologic manifestations developed or progressed in only 1 of 5 patients treated with 75 mg. of folic acid intramuscularly weekly for from eight to seventeen months, but in both of 2 patients who received 50 mg. of folic acid daily orally for six and 11 months respectively. In view of the considerable incidence of neurologic manifestations in patients with pernicious anemia maintained on folic acid this substance probably should not be used as a therapeutic agent in pernicious anemia until at least more is known concerning the nature of this undesirable effect.

Pulmonary Resection for Solitary Pulmonary Abscess.—Hansen says that lobectomy and pneumonectomy have been generally reserved for complicated cases of pulmonary abscess, whereas solitary abscesses without complications are usually treated by pneumonotomy, which is not always successful. Since secondary lobectomy after pneumonotomy involves considerable risk, and since the risk involved in primary lobectomy has become greatly reduced, the idea has suggested itself of performing this operation as the primary intervention. The author reviews observations on 14 patients with solitary pulmonary abscess who were submitted at once to the radical operation. Pneumonectomy was done in 2, lobectomy in 11 and a partial lobe resection in 1 as the primary surgical intervention without preceding surgical drainage. Two of the patients had cavernous tuberculosis with severe putrid mixed infection dominating the condition. In the remaining cases the following indications existed for radical operation: long duration of the abscess; recurrence, severe pneumonitis and hemoptyses, or a site which rendered pneumonotomy risky. One patient died after the operation. The 2 patients with tuberculosis improved considerably in the course of the first few months, but died about one year after the operation. The remaining patients recovered and became able to work far earlier than if pneumonotomy had been done. Radical operation should be the best treatment where long-existing abscesses are concerned and should be considered in cases of newly developed abscesses localized high up in the axilla, under the shoulder blade, mediastinally or in an interlobar fissure. In the latter cases conservative treatment should, if possible, be extended over several months. Radical operation should be done if the abscess persists or recurs. Radical operation is inadvisable in the acute stage.

Surgical Treatment of Hyperparathyroidism.—Liavaag reports 7 cases of hyperparathyroidism treated at the University Clinic of Oslo from 1938 to 1947. The examination of the blood of these patients revealed high calcium and low phosphorus values. The phosphatase values were increased in 3 patients. Six of the 7 patients had renal stones or calcifications and 5 had skeletal changes. Operation revealed an adenoma in the neck in 4 of the patients; another patient was subjected to a second operation elsewhere and an adenoma was found in the anterior mediastinum. Diffuse hyperplasia of the "water-clear cell" type was found in 2 cases. One of these patients had to be operated on again because the glands on one side only were removed, the condition being interpreted as adenoma. No postoperative deaths occurred. In all patients with adenoma the calcium and phosphorus values returned to normal after the operation. Two patients had slight, transient symptoms of tetany. In 1 of 2 patients with hyperplasia the calcium and phosphorus values did not return to normal until the patient was again operated on. In the other patient permanent tetany developed, because all parathyroid tissue in the neck was removed by mistake. The material seems to confirm the American dualistic concept, according to which adenoma and diffuse hyperplasia of the water-clear cells are differentiated. Frozen section should always be made at the operation. Should a water-clear cell hypertrophy be present, subtotal resection of the parathyroids should be done. In the case of adenoma it will suffice to remove it.

Osteomalacia of Spinal Column with Special Regard to Results of Treatment.—In Thaysen's 50 patients, 43 women and 7 men, treated from 1935 to 1946 in Bispebjerg Hospital, the characteristic deformity of the back was seen. Roentgenologic examination as a rule showed pronounced halisteresis. In 24 cases the diet had probably been insufficient in calcium and/or vitamin D for a number of years. Substitution therapy with calcium, usually 10 to 15 Gm. daily, and vitamin D_2, usually 7,000 to 10,000 international units daily, was applied in 44 cases. In 1946 30 patients, 27 women and 3 men, were reexamined. Early and late results were satisfactory; the pain was checked. Most refractory cases were in patients under 60. Other therapy, including physical therapy, was generally without effect. Roentgenologic signs of recalcification were not definitely demonstrable even in patients treated for up to thirteen years; progression seemed to be halted. The patients are believed to represent cases of mild endemic osteomalacia due to nutritional deficiency, but a change in the hormone milieu in older women may pave the way for the development of the disorder, as osteomalacia most often occurs in older women.

Septic Polyarthritis.—In the 3 fatal cases reported by Sylvest in patients with joint diseases, in 2 of whom endocarditis had developed, blood culture revealed Staphylococcus aureus, nonhemolytic streptococci and hemolytic streptococci respectively. In joint sepsis symptoms may occur which occasionally dominate the picture so that clinical distinction between rheumatic fever and sepsis with affection of the joints may be difficult. Study of the records of 73 cases of bacteremia due to hemolytic streptococci, 50 due to nonhemolytic streptococci and 50 due to Staph. aureus showed joint affection in 27 per cent of the first group, 38 per cent of the second group and 38 per cent of the third group, especially the large joints being attacked in the first and third groups and especially the small joints in the second group. Blood culture is recommended in all cases of assumed rheumatic fever in order to disclose possible bacteremia.

*Pulmonary Echinococcosis: Surgical Treatment. J. A. Taiana, E. Schiepati and R. C. Boragina.—p. 441.
*Trigeminal Neuralgia: Medical Treatment: Study on Ethiopathogenesis. M. C. Blanco.—p. 447.

Pulmonary Echinococcosis.—Taiana and his collaborators operated on 29 patients with pulmonary echinococcosis. General anesthesia with cyclopropane-ether and tracheal intubation are procedures of choice. Approach to the lesion was by posterolateral thoracotomy. In presence of uncomplicated small cysts, the operation consists of cystostomy, removal of the parasite, resection of the adventitia, suture of the bronchi, pulmonary suture and closing of the thorax with temporary drainage. Pulmonary resection is the operation of choice in presence of multiple cysts or a large cyst with bronchopulmonary complications. It consists of a typical lobectomy, ligation of the lung pedicle, bronchial suture and temporary drainage of thorax with continuous aspiration. Resection of the lung by this technic is reliable in preventing postoperative complications.

Therapy of Trigeminal Neuralgia.—Blanco believes that trigeminal neuralgia is an allergic reaction of the nerves to circulating bacterial toxins from a focus of chronic infection. The reaction is conditioned by a deficiency of vitamin B_2. He reports good results from penicillin therapy followed by administration of vitamin B_2 in 24 cases. He advises surgical removal of foci of infection, penicillin and vitamin B_2 therapy. Penicillin is given either in one large dose of 500,000 units or in daily dose of 500,000 units divided into three fractional doses and administered for three consecutive days. Vitamin B_2 is given in 15 mg. daily doses for a week or ten days.

*Streptomycin in Pulmonary Tuberculosis in Children. J. L. Alvarez-Sala Moris and R. Navarro Gutiérrez.—p. 370.

Streptomycin in Pulmonary Tuberculosis in Children.—Alvarez-Sala Moris and Navarro Gutiérrez administered streptomycin to 6 children aged 5 to 15 years with pulmonary tuberculosis. They conclude that the daily dose for children should not exceed 1 Gm. This amount is given in four fractional doses with intervals of six hours. The drug should be given up to a total dose of 60 or 100 Gm. in the course of sixty or one hundred days. In the cases reported by them, streptomycin resulted in a cure of acute miliary tuberculosis in 2 cases. In 3 cases of tuberculosis, of lymph nodes or with infiltration, the course of the disease was favorably modified into the attenuated clinical type of the disease.

*Course of Acute Primary Pneumonia Under Chemotherapy. A. Stärkle.—p. 1004.
Early Stage of Syphilitic Aortitis and Its Detection. L. Lazarovits.—p. 1009.

Depot Effect of Procaine Penicillin Suspensions.—Essellier and his co-workers determined the penicillin titer in the serum of 59 afebrile persons with normal kidneys, in 10 febrile patients and in 7 afebrile patients with renal insufficiency to whom intramuscular injections of a procaine salt of penicillin G in sesame oil were given. In 20 of the 59 persons after one injection of 1 cc. of a suspension of 300,000 units of this preparation an effective therapeutic concentration of penicillin—i. e., a titer above 0.03 unit per cubic centimeter—was obtainable on an average for thirty hours with extreme duration values of fifteen to over thirty-six hours. In 14 patients after one injection of 400,000 units of the drug a prolongation of the action of the drug was not obtained, while in 8 patients after one injection of 600,000 units of the drug the duration of its action was prolonged to forty-eight hours. In the 10 febrile patients and in the 7 afebrile patients with renal insufficiency after one injection of 300,000 units of the drug the same effective therapeutic concentration of penicillin was obtainable on an average for over thirty-six hours, with extreme duration values of twenty-one to over thirty-six hours in the first group and of thirty to over forty-eight hours in the second group. The clinical results in 44 patients, 18 with pneumonia, 2 with empyema, 11 with cystopyelitis, 3 with furunculosis, 3 with sore throat, 4 with erysipelas, 2 with endocarditis lenta and 1 with sepsis produced by staphylococci, treated with procaine penicillin G suspensions, were not inferior to those obtained with water-soluble penicillin. Determinations of the titer and clinical experience revealed that in the majority of cases of febrile diseases produced by infection with bacteria sensitive to penicillin, one intramuscular injection of 300,000 units per cubic centimeter of procaine penicillin daily gives a satisfactory therapeutic effect. Severe cases and particularly cases of endocarditis lenta and septic states may require one daily injection of 600,000 to 900,000 units of the drug. The preparation is well tolerated, the injections are painless. Blood eosinophilia may develop. The administration of suspensions of procaine penicillin G in oil is to be considered the most useful method of administration of penicillin.

Acute Primary Pneumonia.—Stärkle reports 196 patients with acute primary pneumonia, caused by pneumococci in the majority of the cases. Administration of sulfonamide compounds is the method of choice in the treatment, while the effect of penicillin in pneumococcus pneumonia is not superior to that of the sulfonamide drugs. Complications, advanced age of the patient and delayed treatment may require additional treatment for which penicillin is to be preferred. This combined treatment is particularly indicated in secondary pneumonias with mixed infections. The pyrimidine preparations are the most effective among the sulfonamide compounds; 0.1 Gm per kilogram of body weight every twenty-four hours, for nine to seventeen days, proved to be adequate. Recurrences were observed in 4 patients (2 per cent). Discontinuation of chemotherapy before the seventh day of the disease, during a phase before immunity is established, may explain the tendency to recurrence. The return of the temperature to normal is not related to the day of the disease when chemotherapy was instituted. Death occurred in 8 cases (4 per cent). The mortality was thus reduced to from a half to a quarter of that which existed prior to chemotherapy. There were 8 cases of empyema and 2 cases of lung abscess. Forty-nine patients (25 per cent) had a serous pleural exudate. This incidence is similar to that of the period before chemotherapy was practiced. The sulfonamide compounds do not exert any effect on this exudate. Resolution of the pneumonic consolidation occurred within three weeks in 157 patients and within four weeks in 13 patients; resolution was delayed for more than four weeks in 11 patients (6 per cent). Chemotherapy did not shorten the time of resolution except in those cases in which treatment was instituted before the exudation of fibrin began. Early resolution depends primarily on individual factors, especially on the youth of the patient, while delayed resolution is caused by extrapulmonary factors such as chronic alcoholism and cardiac disease.

Hellebrine in Cardiac Disorders.—Löffler and his co-workers treated 71 patients with decompensated heart, the majority of whom were aged over 50, by one subcutaneous injection of 0.3 to 0.5 mg. of "helborside" daily for eight to fifteen days. Treatment may be continued with two to three injections per week. "Helborside" is an aqueous solution of hellebrine, an extract of the root of Helleborus niger. The main clinical effects of the drug in the order of their appearance were as follows: frequent and early subjective improvement with reduced dyspnea, slowing of the pulse, increased diuresis and disappearance of signs of pulmonary stasis and hepatic congestion. The drug was well tolerated in the majority of the cases. Treatment must be discontinued in cases in which vomiting, heterotopic ventricular extrasystoles, bigeminy or disturbances of the auriculoventricular conduction occur. Rigid rules cannot be applied to the treatment with hellebrine. The disturbances of rhythm which may occasionally result require control of the pulse and cardiac action before and after each injection of the drug. Because of its rapid effect hellebrine is indicated particularly in cases of excitomotor decompensation resulting in acute left ventricular decompensation in which a rapid but not an immediate effect is required; in the latter case strophanthin or ouabain may be preferred. Because of the pronounced effect of hellebrine on the cardiac rhythm it is useful in all cases of tachycardia regardless of their nature, but caution is required in cases of tachyarrythmia with ventricular extrasystole.

Book Notices

Zinsser's Textbook of Bacteriology: The Application of Bacteriology and Immunology to the Diagnosis, Specific Therapy and Prevention of Infectious Diseases for Students and Practitioners of Medicine and Public Health. Revised by David T. Smith, M.D., Professor of Bacteriology and Associate Professor of Medicine, Duke University School of Medicine, Durham, N. C., and others. Ninth edition. Fabrikoid. Price, $10. Pp. 992, with 251 illustrations. Appleton-Century-Crofts, Inc., 35 W. 32nd St., New York 1, 1948.

The former eight editions of this book had Dr. Zinsser as one of the editors. With the passing of Dr. Zinsser, the book is dedicated to the previous authors, Hiss, Zinsser and Bayne-Jones, and now is revised by a team of seven authors from the faculty of Duke University.

The outline and arrangement are similar to those in the eighth edition. A section on antibiotics is added and the discussion on sulfonamide compounds is enlarged. A chapter on pleuropneumonia organisms has been added. An introductory paragraph to chapters dealing with specific infections emphasizes the public health aspects of the disease. Much recent material is added. The sections on bacterial metabolism, immunology, fungus and viral diseases have been rewritten. One hundred and eighty-two new illustrations have been added including electron micrographs of bacteria and viruses.

Some chapters have had slight if any revision. For example, the chapter on bacterial ecology and flora of the normal body has not been brought up to date. The closing paragraph of this chapter refers to important developments which were under way when the last edition was prepared. Only three pages are devoted to classification in chapter 10.

In chapter 11, entitled "Pathogenicity and Virulence," on page 140 the following statement is made: "However, in our opinion, a virulent organism should be considered as one which possesses the power to produce disease even when introduced in extremely small doses—in fact, virulence can be measured only in terms of the number of organisms which must be introduced to cause disease." In two paragraphs below this statement on the same page, under the heading "Toxin Production," the following statement is made: "In some diseases such as botulism and tetanus, the virulence of the bacterium is dependent almost exclusively upon its ability to produce exotoxins."

In chapter 32, on "Salmonella and Salmonellosis," page 443, the following statement is made: "In recent years, however, typhoid fever has been brought under control by means of sanitary engineering and active immunization programs, while the diseases produced by the other 150 species of the Salmonella group have become relatively more frequent." Since the typing of Salmonella is comparatively recent and the reporting of Salmonella infections, at least with the lesser pathogenic species, is incomplete, there is doubt as to whether some of the Salmonella infections are becoming more frequent.

In view of the stupendous task of revising a book of this magnitude, the number of errors are few, and, in general, controversial issues are presented without bias. The book can be highly recommended as a textbook for medical students. The printing is good and the illustrations are excellent. Each chapter is well documented with a bibliography.

Direct Electrocardiography of the Human Heart and Intrathoracic Electrocardiography. By Franz M. Groedel, M.D., Attending Cardiologist, Beth David Hospital, New York, and Paul R. Borchardt, M.D., F.C.C.P., Attending Physician, St. Anthony's Hospital, New York. Cloth. Price, $9. Pp. 224, with 67 illustrations. Brooklyn Medical Press, Inc., P. O. Box 99, Station H, New York 25, 1948.

The basis of this book is the examination of intrathoracic electrocardiograms obtained by the closed method in 100 patients on whom pneumonolysis was performed, and, in addition, similar electrocardiographic data obtained by the open method. This gave the authors the opportunity of obtaining the configuration of the human electrocardiogram at the surface of the auricles and ventricles as well as that over the great vessels, diaphram and lungs.

The monograph crystallizes the recent work of the authors and documents these methods and findings in detail. The format is excellent and the profuse illustrations are well reproduced. They form a valuable addition to the data on electrocardiography which helps to round out data obtained by the customary methods and more recently by intracavity leads.

The literature is adequately covered, but one is left with the impression that the major contributions in electrocardiography have been made by the senior author and his associates. The reviewer has little disagreement with the factual data presented, but takes sharp exception to some of the authors' conclusions drawn as to the theory of the genesis of the electrocardiogram. The last two chapters of this monograph are complex, polemic and at times illogical. There seems little justification at this late date to revive, as the authors have done, the long buried duality theory of the electrocardiogram even in modified form. The monograph is recommended for the cardiologist because of the excellent documentation of the electrical changes occurring during the heart cycle within the chest and also as a warning of the pitfalls inherent in this type of *a posteriori* deductions.

Strabismus: A Clinical Handbook. By George J. Epstein, B.A., M.D. Fabrikoid. Price, $5. Pp. 214, with 76 illustrations. The Blakiston Co., 1012 Walnut St., Philadelphia 5, 1948.

In this small volume the author feels that "although the literature in periodicals on all phases of strabismus is abundant, the necessity exists for the organization of our current knowledge and beliefs into a treatise which shall present the subject with a maximum of conciseness and clarity, and yet afford ample coverage of the field." Certainly the book fulfils this goal. Controversial theories are considered in detail and methods for the correction of strabismus are ably enunciated.

In the preface the author states that "To the pediatrician or general practitioner at whose door the cross-eyed child frequently knocks first, a study of the methods of diagnosis, differential diagnosis and the indications for treatment may be of value. Particularly is this the case in the light of the belief held by the overwhelming majority of ophthalmologists that the diagnosis of strabismus must be made, and its treatment instituted, as early in life as possible." This phase of the book could be improved, particularly in view of the fact that the pediatrician and general practitioner need shock to change ideas which they have been taught for years.

The format is excellent, the chapters outlined in advance, the illustrations are excellent, references terminate each chapter and an ample index ends the contents of the book. Dr. Epstein has accomplished a good work.

Die primäre Tuberkulose bei Erwachsenen und Kindern und ihre Entwicklung. Von Dr. Med. St. J. Leitner, Privatdozent für innere Medizin der Universität Bern, unter Mitarbeit von Dr. R. M. Steinmann. Paper. Price, 15 Swiss francs. Pp. 157, with 32 illustrations. Hans Huber, Marktgasse 9, Bern 16, 1948.

This volume contains an extensive discussion of the evolution of primary tuberculosis in adults and children. The author presents the results of investigations of 160 adults and 106 children with recent primary tuberculosis. The patients were followed from two to eight years after their first admissions to hospitals. This is a selected group because all were hospitalized and therefore are not comparable to persons who contract primary tuberculosis but do not require hospitalization or medical care. The author does not state whether his patients had been on routine tuberculin testing schedules before they became infected so as to know approximately when the primary infection occurred. This information is essential to the study of the evolution of tuberculosis in every case. Without it one cannot be certain whether the lesions found among those ill from tuberculosis are of the primary or reinfection type of disease. All of Dr. Leitner's patients were reactors to tuberculin at the time that he saw them with symptoms or other demonstrable findings. He states that under favorable circumstances the symptoms subsided and sedimentation rates and blood pictures became normal in four weeks. However, no improvement was seen in this time as manifested by roentgen shadows. Disappearance of shadows usually took several months or even years. He believes that hospitalization should not be discontinued until there is definite decrease of the roentgen findings.

Erythema nodosum occurred in 33.7 per cent of the adults and in 6.6 per cent of the children. This is an interesting observation and is similar to that reported by several Scandinavian authors. It differs widely from observations made in the United States, where erythema nodosum has been reported as a relatively rare finding among children and adults with recently developed primary tuberculosis. Dr. Leitner points out that erythema nodosum is not always the result of primary tuberculosis, but he believes this disease should be considered in every case. Pleurisy with effusion is reported in 31.8 per cent of adults and 21.7 per cent of the children in Dr. Leitner's group. Apparently this condition also occurs less frequently among those who contract primary tuberculosis in the United States. Several important aspects of the development of the reinfection type of tuberculosis are discussed, such as hematogenous spread and exogenous reinfection.

Thirty-two good illustrations are included, mostly reproductions of roentgenograms. More than 300 references to the literature are listed. This book is well written and is thought provoking, since it includes several highly controversial subjects. However, much of the controversy may be due to unlikeness in the material which various authors present, dissimilarity in prevalence of the disease in the places where they work and differences in interpretation of findings, rather than to inherent variations in the disease itself.

Functional Neuro-Anatomy. By A. R. Buchanan, M.D., Professor of Anatomy, University of Colorado School of Medicine, Denver. Fabrikoid. Price, $6.50. Pp. 242, with 199 illustrations. Lea & Febiger, 600 S. Washington Square, Philadelphia 6, 1948.

This is an excellent text on neuroanatomy. It is labeled functional and justifiably so because the author has arranged and discussed the various structures as one meets them. These discussions are complete for each tract that the reader meets, and therefore the student is made acquainted with all the various parts of each pathway at one and the same time. This style of text writing is much more practical than the older method of describing various topographic levels. The book contains 242 pages and has 199 illustrations. The reading is very easy and the language is extremely simple. The student needs no dictionary to understand fully this important part of neurology. There are 29 chapters, starting with the development and histogenesis of the nervous system and ending with a chapter on the interstitial tissue of the central nervous system. This is the first edition of the author's mimeographed syllabus which has been available to his students in neuroanatomy. The book is highly recommended for all medical students, neuropathologists, clinical neurologists and neurophysiologists. It is one of the best texts in neuroanatomy.

A Practical Manual of Diseases of the Chest. By Maurice Davidson, M.A., M.D., F.R.C.P., Physician to the Brompton Hospital for Consumption and Diseases of the Chest, London. Oxford Medical Publications. Third edition. Fabrikoid. Price, $16.50. Pp. 670, with 269 illustrations. Oxford University Press, 114 5th Ave., New York 11; Amen House, Warwick Sq., London, E.C. 4, 1918.

The third edition of this excellent book brings the reader up to date on almost all phases of chest disease work. A sizable number of new illustrations have been added, and various new developments have been included since the second edition was published in 1941. The third edition contains two new chapters, one on sarcoidosis and the other on pulmonary cysts. The first section of the book consists of chapters on anatomy and physiology of the respiratory system, radiology, the relation of chest disease to general medicine and pathology, and systematic examination in diseases of the chest.

In appropriate sections all of the diseases attacking the organs of the upper respiratory tract, the lower respiratory tract, the lungs, pleura and mediastinum are presented with reference to diagnosis, treatment, prognosis and prevention.

In the section on diseases of the lungs, the pneumonias, pulmonary fibrosis and the pneumonoconioses are discussed in separate chapters. Five chapters devoted to pulmonary tuberculosis contain excellent presentations of pathology, etiology, epidemiology, diagnosis, treatment and prevention.

The sections on intrathoracic suppurations and new growths contain good chapters on empyema, abscess, various malignant conditions, as well as cysts of the lungs and pleura. This book of 670 pages, with 268 excellent illustrations, contains so much new material and such a valuable store of fundamental information that it should be available to all physicians working in the field of diseases of the chest.

Radioactive Indicators: Their Application in Biochemistry, Animal Physiology, and Pathology. By George Hevesy. Cloth. Price, $10. Pp. 556, with 97 illustrations. Interscience Publishers, Inc., 215 Fourth Ave., New York 3, 1948.

According to the preface, this book was written in the Institute for Theoretical Physics of the University of Copenhagen and the Institute for Research in Organic Chemistry of the University of Stockholm; it was completed in the Donner Laboratory of the University of California. It presents the amazing array of facts that have been learned but recently by the use of radioactive tracer substances in chemistry and biology. Despite the amount, variety and newness of this information, it is presented coherently, readably and with the exactness of detail that is in the best European tradition.

The following are the larger divisions of the text: production of radioactive isotopes; list of radioactive isotopes of possible interest in tracer work; atomic interchange; applications in chemical analysis; absorption, distribution and excretion of elements; permeability of phase boundaries; turnover studies; path of intermediary reactions; skeleton metabolism; biochemistry of red corpuscles; shortcomings of radioactive indicators. A Segré chart, to be found in a pocket inside the back cover, repays careful study, for it orients all the stable and radioactive isotopes with respect to each other and presents the new artificial elements in an instructive light. Illustrations include a number of radioautographs. The text includes many items of special interest such as the pharmacology of plutonium. There are good subject and author indexes. The quality of the printing is excellent and the appearance of the entire book attractive. The book will be found interesting by the general reader and of permanent value to the specialist.

A Short Practice of Surgery. *By Hamilton Bailey, F.R.C.S., F.A.C.S.,* F.I.C.S., Surgeon, Royal Northern Hospital, London, and R. J. McNeill Love, M.S., F.R.C.S., F.A.C.S., Surgeon, Royal Northern Hospital. With pathological illustrations by L. C. D. Hermitte, M.B., Ch.B., Pathologist, Royal Infirmary, Sheffield. Part Two. Eighth edition. Cloth. Price, £2.12s.6d per set of 5 parts. Pp. 225-420 with 260-530 illustrations. H. K. Lewis & Co., Ltd., 136 Gower St., London, W.C. 1, 1948.

The seventh edition (1946) of this book was presented in one rather large volume. The eighth edition is now being published in five parts, part II of which is available for review. This includes the part of the book dealing with the gastrointestinal tract (excepting rectum and anus) and the peritoneum. The smaller volumes are easier to handle than one large volume, but this advantage might be offset by increased difficulty in looking up specific subjects. The new edition has been brought up to date by inclusion of such subjects as vagotomy for peptic ulcer, transthoracic approach to lesions of the cardia and esophagus, esophageal atresia of the newborn, esophagogastrostomy for cardiospasm, newer hepatic function tests and portocaval shunts for portal hypertension.

Outline of Physiology. By William R. Amberson, Ph.D., Professor of Physiology, University of Maryland, Baltimore, and Dietrich C. Smith, Ph.D., Associate Professor of Physiology, University of Maryland Second edition. Cloth. Price, $5. Pp. 502, with 193 illustrations by Norris Jones and William Loechel. Williams & Wilkins Co., Mount Royal and Guilford Aves., Baltimore 2, 1948.

This is an excellent, brief, sometimes too elementary text which starts out to be a treatise on general or comparative physiology but finally evolves into a stimulating presentation of elementary human physiology, although some of the material is a bit profound for the reader who is best able to profit by its use. Textual matter is sound and reserved. The book can be recommended highly for college classes and even in some sections as supplementary reading for medical students.

A Brief History of the South Carolina Medical Association to Which Are Added Short Historical Sketches of Various Medical Institutions and Societies of South Carolina. Published by the South Carolina Medical Association at its Centennial Meeting, Charleston, 1948. Cloth. Pp. 197, with illustrations. South Carolina Medical Association, Charleston, 1948.

This brief sketch of the history of the South Carolina Medical Association is of particular interest to the physicians of South Carolina for whom it was prepared as a part of the centennial celebration of that state association. It is a valuable addition to the literature on the history of the medical profession in the United States.

Queries and Minor Notes

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request

TIME OF OVULATION

To the Editor:—I have been consulted by a young married woman relative to avoidance of pregnancy. Both she and her husband have religious scruples regarding use of contraceptives. Her menses are irregular and occasionally she will skip a month or two. She has tried to determine times of ovulation by taking rectal temperatures but with indefinite results. I have been under the impression that the ten days immediately preceding menstruation was a relatively safe time for intercourse but as beginning of menstruation is unpredictable this does not help. Is there definiteness regarding time of ovulation following a menstrual period?

M.D., Alabama.

Answer.—Ovulation is associated with the menstrual period which follows and not with the one which precedes it. Ovulation occurs about fourteen days before the onset of the following menstrual bleeding in most women. In those who menstruate from twenty-six to thirty days, an ovum is extruded from the ovary sometime between the tenth and the seventeenth day of the cycle. These days are the so-called fertile days and are to be avoided by women who practice the rhythm method of conception control. Women with cycles which differ from the twenty-six to thirty day type must calculate the days when ovulation can occur and, of course, these days are different from those for women who have a twenty-six to thirty day cycle. There are various ways of trying to determine the day of ovulation in this case. 1. Examination of the endometrium. It is generally believed that the changes in the uterine endometrium indicate accurately what is going on in the ovary. Whereas in nearly all cases the finding of luteal endometrium by biopsy or curettage indicates that ovulation has taken place, it is extremely difficult to determine the exact day when it took place. Even if this could be determined, it would not follow that ovulation would take place in subsequent months on the same day. 2. Hormone studies of the blood and urine. Kurzrok claims that there is a rise in gonadotropin excretion twenty-four hours before ovulation, and D'Amour observed an increase in this hormone between the twelfth and the sixteenth day before the onset of bleeding. In many cases there was a second rise just before menstruation began. There were also two peaks of estrogen output which usually preceded the increase in gonadotropin. Venning and Browne found that excretion of pregnandiol, an excretion product of progestin, rose to a plateau after ovulation and then fell abruptly just before the onset of flow. Further studies are necessary before these hormone studies can prove useful. 3. Pommerenke and Viergiver determined the length of the ovulatory phase in the normal menstrual cycle on the basis of the increased quantity and decreased cellularity of the cervical mucus secreted at this time. This phase of increased secretion was found to vary from three to seven days in length and to occur later in cycles of longer length. The shift in basal temperature was found to occur, with rare exceptions, only during this phase of increased mucous secretion. The day of maximal mucus production usually occurred sixteen to twelve days before the onset of the subsequent menstrual period regardless of the length of the cycle. A study of the cervical mucus cycle together with the basal temperature is suggested as a possible aid in planning pregnancies. 4. Vaginal smear. Papanicolaou claims that the vaginal epithelium of human beings, like that of many laboratory animals, undergoes cyclic changes during the month. However, not all agree that such changes can be detected regularly; therefore the study of vaginal smears, although of value, has limited applicability.

D'Amour, who has done considerable work in endocrinology, studied 20 menstrual cycles in 5 women, using concurrently four to six of the following sources of information: gonadotropin assay, estrogen assay, pregnandiol determination, vaginal smears, body temperature and subjective experiences. The purpose was to evaluate the validity of the tests on the basis of uniformity in the occurrence of positive responses and synchrony of their appearance. It was concluded that (1) subjective experiences were valueless as tests for ovulation; (2) body temperature fluctuations were not sufficiently regular or clearcut to be reliable; (3) uniformity of results of hormonal assays and vaginal smears confirmed the validity of each, and a certain sequence of events appears typical of the normal cycle, and (4) because of its sharpness and its apparent close association with ovulation, the gonadotropin peak, occurring in the midinterval, is most indicative of the exact time of ovulation.

Obviously it is not easy to tell the exact day of ovulation. Recently, D. P. Murphy and E. J. Farris (The Journal, Sept. 4, 1948, p. 13) reported excellent results with artificial insemination based on Farris' rat ovulation test. The exact day of ovulation is determined by the injection of the wife's urine into immature female white rats of the Wister strain.

TALCUM POWDER DUST

To the Editor:—What are the dangers of exposure to moderate amounts of talcum powder dust by inhalation? I refer to air breathed by operating room helpers engaged in powdering surgical gloves. M.D., New York.

Answer. — Prolonged exposure to talcum powder dust in sufficient concentrations is capable of producing a disabling pneumonoconiosis. In a study of 221 men in the mining and milling industry in northern New York reported by W. Siegal, A. Smith and L. Greenburg (*Am. J. Roentgenol.* **49**:11, 1943) advanced fibrosis was found in 32 men, all of whom had worked in tremolite talc for ten years or more. The fibrosis was a fine diffuse type with a roentgenographic appearance of granulation or nodulation on a hazy background. It was frequently accompanied by dyspnea, cough and fatigue. There was some evidence that fibrosis was characterized by an increased susceptibility to tuberculosis.

N. Millman reports in *Occupational Medicine* (**4**:391, 1947) a case in which exposure to talc in the cosmetic industry caused generalized pneumonoconiosis of a nodular type. The man had been exposed to the atmosphere of talcum powder-mixing rooms of cosmetic plants for twenty-four years. The dust count in the general atmosphere of the powder mixing department in one plant studied ranged from 15,900,000 particles to 236,000,000 particles per cubic foot of air. At the 1947 meeting of the American Conference of Governmental Industrial Hygienists, the Committee on Threshold Limits recommended that the amount of talc in the working atmosphere based on an eight hour working day not exceed 20,000,000 particles per cubic foot of air.

Although the inhalation of talc dust is a potential industrial hazard, working conditions of operating room helpers do not parallel those of miners and millers. The rotation of personnel and the few hours spent in powdering gloves eliminate most of the danger. Periodic physical examination and roentgenograms of the chest are urged for all persons who are exposed for prolonged periods. Suspected dust hazards should be controlled.

CONGENITAL IMPETIGO

To the Editor:—A 24 year old white housewife expects to be delivered of her third child in April 1949. Her first infant died at one month of "congenital impetigo." The second infant was born unattended at term and had impetiginous lesions of its nail beds which later spread to involve most of the body orifices (nares, ears and genitalia). The lesions were diagnosed as pemphigus neonatorum (Ritter's). The infant did fairly well under a high vitamin and caloric regimen with penicillin ointment and methylrosaniline chloride locally, only to succumb to bronchopneumonia at 5 months. All present findings are normal. Do you consider cesarean section justified in this case? M.D., Maryland.

Answer.—Since there is a possibility that the mother's vagina may harbor staphylococci and streptococci which may be the cause of the "congenital impetigo" in the first baby and the pemphigus neonatorum in the second, studies should be made of the bacterial flora of the vagina. Intravaginal medication should be of considerable help in bringing about the removal of harmful bacteria. It is much better to use vaginal suppositories of penicillin than vaginal instillations of merbromin N. F. (mercurochrome®). There is no need to perform a cesarean section on this patient to avoid infection of the child.

FLUORESCENT LIGHTING AND ALOPECIA

To the Editor:—What are the possibilities of fluorescent lights' producing irritation of the scalp and alopecia? In a reconverted war plant where a number of men and women do clerical work, 1 of my patients states that several of the workers are experiencing such difficulties, and she is losing her hair at an excessive rate. O. S. Philpott, M.D., Denver.

Answer.—Evidence for suspicion that exposure to fluorescent light causes dermatitis of the scalp and alopecia is lacking. The energy from a fluorescent lamp is just visible energy, no different from that of other lighting lamps, and the glass used is like ordinary window glass.

RESTING AFTER MEALS

To the Editor:—The following is a quotation from an article in a newspaper. Is there any scientific basis for it? "A nap at midday or immediately after evening meal is all right for adults up to middle age, especially for those who do real physical work. It is not so good for elderly adults and especially for those who are of *sedentary habit* and those who carry a handicap of slacker flesh. The reason why it is a bad habit for the sedentary, overfed, elderly person to nap after dinner is because it predisposes to cerebral thrombosis from slowing of the *circulation.*"
P. J. Imperato, M.D., Brooklyn.

Answer.—It is in general true that recumbency with sleep immediately after meals is less satisfactory than rest in such a position before meals. This is particularly true in older persons and in fact is an old medieval rule of health which still holds. The recumbent position is less satisfactory for the circulation than the upright position and the increased activity of the digestive tract after meals is best carried out in the upright seated position.

HYDROTHERAPY IN PSORIASIS

To the Editor:—A patient with fracture of the right humerus was treated last year. This patient had psoriasis of the elbows. At the time the patient returned to Boston he was at the stage of bony union where physical therapy and hydrotherapy were indicated. He received this treatment, including the whirlpool for the right arm, all summer while at home. He returned to me with the right elbow (the fractured member) completely healed with healthy skin. The left elbow was at the same stage as when seen at the last visit. *Could the whirlpool be the reason for* the improvement?
A. R. Taylor, M.D., Fort Lauderdale, Fla.

Answer.—The whirlpool bath undoubtedly exerted a beneficial effect in this case, but the principle of such treatment is not new. Many dermatologists recommend to patients with psoriasis that they "soak in a tub" daily and for prolonged periods prior to applying their salves. It has been a practice for many years.

WEIGHT OF ANATOMIC STRUCTURES

To the Editor:—What are: (1) the approximate weight of the total skeletal *muscles in a human adult; (2) the approximate weight of the skeletal* system in a human adult; (3) the approximate weight of the integument, or skin, and (4) the approximate weight of the total nervous system, including the brain?
David I. Macht, M.D., Baltimore.

Answer.—There are many variations. Anatomists report average approximate weights in a strong adult man of good proportions and good health, weighing 150 pounds as follows:

	Weight, Pounds	Percentage
Skeletal system, fresh	24	16
Skeletal muscles	60	40
Skin alone	7½	5
Attached subcutaneous tissue	15	10
Nervous system, including brain, cord and nerve stems but not membranes or intramembranous fluid outside brain and cord	3⅜	2¼

VITAMIN E IN DIABETES

To the Editor:—A diabetic patient referred me to the article entitled "New Diabetes Treatment with Vitamin E" in the December issue of *Magazine Digest*. What further information can you supply regarding the value of *this medication? Information on this subject comes from the Shute Insti*tute for Clinical and Laboratory Medicine, London, Ontario, Canada.
Albert Tormey, M.D., Madison, Wis.

Answer.—Several papers have been published from the Shute Institute suggesting advantage from the use of large doses of alpha-tocopherol in the treatment of vascular disease. Confirmatory reports from other centers have not come to our attention. The observations commented on in the *Magazine Digest* have also not been confirmed. Until such confirmation has been obtained the routine use of alpha-tocopherol in the treatment of diabetes is not recommended.

PROCAINE PENICILLIN IN CHILDREN

To the Editor:—Is there objection to giving almost an adult dose of penicillin in wax and oil to a baby a few months of age? If a procaine preparation is used what is the dose for children? Has the procaine preparation produced bad reactions?
M.D., Pennsylvania.

Answer.—The usual dosage of penicillin in wax and oil is 300,000 units contained in 1 cc. This dosage in a baby a few months of age, injected intramuscularly, would probably produce a high blood level. A smaller dose for such an infant could probably be depended on unless the infection for which the penicillin was used was of particular virulence or severity.

The newer preparation, procaine penicillin, which is a chemical compound suspended in oil and is free flowing because it contains no wax, may be used in infants and children in the following dosage: Infants from birth to one year, ½ cc. or 150,000 units, and in children 1 year and over, 1 cc. or 300,000 units. These dosages have shown adequate penicillin blood levels over twenty-four hour periods. Procaine penicillin preparations have not led to bad reactions. As wax is lacking in this preparation, local nodules do not occur.

HERPES SIMPLEX IN MENSTRUATION

To the Editor:—A woman, aged 40, has had what seems to be recurrent herpes simplex of the right buttock for two years. Recurrences coincide *each month with the menstrual period.* There is usually a sudden onset shortly before the menses with aching and pain radiating down the right leg followed by the appearance, at onset of menstruation, of a small group of superficial vesicles on a reddened base. After a day or two the *ruptured* vesicles become covered with a thin, straw-colored or bloody crust. This gradually disappears, leaving a reddened area which gradually fades. Her greatest discomfort occurs before the eruption appears. Recurrences are always in an area about 2 inches (5 cm.) in diameter, and on several occasions the recurrence has been in the identical site of the previous lesion. The lesion is usually ⅜ to ½ inch (0.96 to 1.27 cm.) in diameter. At times the lesions occur after the menstrual period or precede it. *The patient has had an occasional herpes of the lips for* many years.

Past history reveals Parinaud's conjunctivitis two years ago; acute vertigo, tinnitus and sudden deafness in right ear ten years ago, and frequent atypical migraine headaches and some mild tinnitus and vertigo on occasion. Menses are regular and normal. She has never been pregnant. The pupil of the right eye has been larger than the left for several years. Treatment has consisted of fifteen smallpox vaccinations at one to two week intervals; ten injections of 5 cc. of her own blood into the gluteal muscles; local application of thiamine in glycerin and oral administration of thiamine. Treatment has not altered the course or recurrence.

Please suggest treatment.
M.D., Kentucky.

Answer.—One must always give consideration to an endometrial implant such as has been recently reported by Schlicke in The Journal (132:445, 1946). Biopsy of the area would aid in making a correct diagnosis. A more likely possibility is that the acute vertigo, tinnitus and sudden deafness could have been symptoms of Ménière's disease and that the patient now has a histaminic reaction which manifests itself as described. The patient should be desensitized to histamine according to the technic of Horton and adjusted to a maintenance dose. This should bring regression of the symptoms. The third possibility is sensitivity of the patient to her own estrogen. Large doses of vitamin B might aid in controlling this situation. Depression of the menstrual periods produced by large dosages of estrogen or androgen would aid in measuring the role of the menstrual flow in the occurrence of these lesions.

THROBBING SENSATIONS IN THE HEAD

To the Editor:—A white male patient, age 48, of professional occupation, complains of throbbing or pulsations in the head, neck and chest while sitting down. In the last two years he noticed that while relaxing in a *chair or in bed he has a pulsating or throbbing sensation when head is* resting on back of soft chair or on a pillow. No difference occurs in changing position of his head when lying in bed. Blood pressure is 126 systolic and 80 diastolic, pulse rate 80, and lesions of heart, checked by electrocardiogram and other tests, are absent. What is the prognosis and what can be done to help this patient?
M.D., Pennsylvania.

Answer.—Granting that the information as to absence of any lesion of the heart or blood vessels is correct, there seems to be no basis for connecting the symptoms with any other kind of physical pathology. Many persons are inclined to attach too much importance to pulsations and throbbings once they have become accustomed to detecting them. Such a tendency is noted especially in psychoneurotic conditions. Reassurance about the particular symptom may be of some help. Ordinarily, adequate history will reveal other symptoms than the throbbing and will serve as a basis for psychotherapy.

SUSPENSORIES AND SPERMATOGENESIS

To the Editor:—In The Journal, Nov. 27, 1948, *your answer to the query* about the continued wearing of a suspensory states that there should be no deleterious effect on spermatogenesis. This answer is not correct.

We know that in animals with extra-abdominal testes normal body temperature destroys spermatogenesis. That is the reason *that there is* a dartos muscle in the scrotum which relaxes and cools the testes when environmental temperature increases and contracts in the cold. This thermoregulatory function of the dartos is generally recognized today. The wearing of a suspensory annuls this dartos action and is therefore unphysiologic and may allow the temperature of the testes under certain conditions to rise to above that which it should be normally. I have seen spermatogenic function improve with no other treatment than the removal of such a support.

SPECIFIC THERAPY OF BACTERIAL INFECTIONS OF CENTRAL NERVOUS SYSTEM

HARRY F. DOWLING, M.D.
LEWIS K. SWEET, M.D.
HAROLD L. HIRSH, M.D.
and
MARK H. LEPPER, M.D.
Washington, D. C.

Therapeutic agents are now available to combat most bacterial infections of the central nervous system. Consequently, proper treatment depends on (1) prompt diagnosis of the disease, (2) prompt determination of the etiologic agent and (3) selection of the appropriate drug or antibiotic. Since such selection depends on the causative organism in any given case, we have arranged the present discussion according to the bacteria responsible for the various diseases.

MENINGITIS CAUSED BY GRAM-NEGATIVE COCCI

Meningococcic Meningitis.—Meningococcic meningitis is the most frequent type of meningitis. Excellent results have been obtained with sulfadiazine or sulfamerazine. The dose for adults is 6 Gm. immediately and 1 Gm. every four hours and for children 70 mg. per kilogram (½ grain per pound) of body weight immediately and 150 mg. per kilogram (1 grain per pound) for each twenty-four hours thereafter, at four hour intervals. Comatose patients should be given an initial intravenous dose of 0.5 per cent solution of the sodium salt in sixth-molar lactate or isotonic sodium chloride solution. Subsequent doses are preferably given by stomach tube or by mouth, since this insures more constant blood levels, although the subcutaneous route may be used instead. Sodium bicarbonate, 6 Gm. at the start and 3 Gm. every four hours, should be used concomitantly in order to minimize the possibility of the formation of renal calculi. We[1] have recently obtained successful results in a few patients with meningococcic meningitis by the use of Nu-445,[2] a sulfonamide drug which is very soluble and has not yet been observed to cause renal calculi. Many more patients will have to be treated, particularly during an epidemic, before it will be possible to say that this drug is as good as sulfadiazine or sulfamerazine.

We have not found it necessary to employ penicillin routinely in meningococcic meningitis except in patients with a fulminating infection (the Waterhouse-Friderichsen syndrome). It is also used in patients who do not respond to sulfonamide drugs within twenty-four to forty-eight hours. Probably the most satisfactory way to administer penicillin for these purposes is in doses of 1,000,000 units intramuscularly every two hours, as will be shown in the discussion on pneumococcic meningitis.

The effects of therapy may be judged by (1) the rapidity of the fall in temperature and decrease in toxicity, (2) the disappearance of the meningococci from the cerebrospinal fluid and the increase in its dextrose content and (3) the decrease in the leukocyte count of the cerebrospinal fluid. Treatment with sulfonamide compounds and penicillin may be discontinued one week after the temperature drops if the patient is doing well in all other respects. The results which we have obtained[3] with this regimen are given in table 1. It will be seen that the fatality rate for all cases was 8.8 per cent and that it increased progressively with age. The fatality rate for comatose patients was double that for the entire series.

Gonococcic Meningitis.—Gonococcic meningitis is a much rarer condition. We have observed only 2 patients since the sulfonamide compounds have been available. Both recovered promptly under sulfonamide therapy. We recommend the same treatment as for the meningococcic type.

MENINGITIS CAUSED BY GRAM-POSITIVE COCCI

Pneumococcic Meningitis.—Pneumococcic meningitis is the most frequently observed disease in this group. The orthodox method of treatment consists of daily intrathecal injections of 10,000 to 20,000 units of penicillin plus sulfonamide drugs and 500,000 to 2,000,000 units of penicillin systemically. Intrathecal administration of penicillin has been considered necessary because many investigators have found that when penicillin is administered systemically, diffusion into the cerebrospinal fluid is irregular or does not occur.

Previous studies in our laboratory[4] have shown that several factors are important in obtaining and maintaining a satisfactory concentration of penicillin in the cerebrospinal fluid: (1) sufficiently large amounts of penicillin must be administered systemically; (2) the penicillin must be given for a certain interval before it appears in the cerebrospinal fluid, and (3) penicillin diffuses into the cerebrospinal fluid more freely in the presence of inflammation. Schwemlein and his co-workers[5] reported that detectable concentrations of penicillin were present in the spinal fluid of patients who received

20,000,000 units or more of penicillin during the course of twenty-four hours by continuous intravenous injection. We[6] gave 1,000,000 units intramuscularly at two hour intervals to 13 patients with and without meningitis and found that small amounts of penicillin were present in all patients within the first two hours after the first injection. After eight hours the spinal fluid concentrations in the patients with meningitis were between 0.08 and 2.5 units per cubic centimeter. We[6] have treated 22 patients with pneumococcic meningitis with doses of 1,000,000 units every two hours. Three patients also received a single intrathecal injection of penicillin and 12 received sulfonamide compounds. Eight patients died of meningitis, giving a case fatality rate of 36 per cent. This compares favorably with a fatality rate of 62 per cent among the 66 patients previously treated by us with smaller doses of penicillin systemically plus repeated intrathecal injections of penicillin. We therefore advocate as the best treatment for pneumococcic meningitis available today 1,000,000 units of penicillin intramuscularly every two hours. Patients in coma or in extremis when treatment is begun may be given a single initial intrathecal dose of penicillin in addition. Sulfonamide compounds do not appear to be necessary when these doses are used.

Meningitis Caused by Staphylococci and Beta Streptococci.—Meningitis caused by these organisms is usually treated by multiple intrathecal injections plus systemic doses of penicillin. We have successfully treated 1 patient with meningitis caused by beta hemolytic streptococci with systemic doses of 1,000,000 units of penicillin every two hours and without intrathecal therapy. We have not had an opportunity to treat any patients with staphylococcic meningitis in this manner, but believe that this treatment should be as successful as in pneumococcic meningitis.

MENINGITIS CAUSED BY GRAM-NEGATIVE RODS

Hemophilus Influenzae Meningitis.—This type of meningitis responds well to streptomycin. Infants and young children may be given 1.5 Gm. per day, divided into 4 six hour intramuscular doses. Adults should receive 3 Gm. per day. Daily intrathecal injections of 25 mg. are also given to young children and 50 mg. to older children and adults.

Although streptomycin is usually successful when given alone, we believe that sulfadiazine should be given at the same time because of its effect on H. influenzae, because it may help to prevent the appearance of streptomycin-fast organisms and because it will inhibit the multiplication of gram-positive organisms during streptomycin therapy. The doses should be the same as in meningococcic meningitis.

When treatment is delayed or the patient is critically ill when therapy is started, or if no improvement occurs after forty-eight hours of streptomycin-sulfadiazine therapy, specific rabbit antiserum should be given in doses of 100 to 200 mg. of antibody nitrogen. About 90 per cent of patients will recover when they are treated in this manner.

Meningitis Caused by Other Gram-Negative Rods.—Meningitis caused by other gram-negative rods, such as Escherichia coli, Pseudomonas aeruginosa (pyocyaneus), Klebsiella pneumonia (Friedländer's bacillus) and Aerobacter aerogenes should be treated in the same way as H. influenzae meningitis, except that specific serum would not be used. Since these types of meningitis are often an end stage of an overwhelming infection, the prognosis is uncertain and often depends on factors other than the meningitis itself.

TUBERCULOUS MENINGITIS

The early results with streptomycin in this disease appeared to be excellent. Clinical arrest occurs in one fourth of the patients. The results are especially favorable in patients who had meningitis without miliary tuberculosis. Not all of the patients with arrested disease recover, however. The longer they are followed the higher becomes the percentage of relapses, until now it seems likely that no more than 5 or 10 per cent of patients with tuberculous meningitis will recover completely and most of these will have some permanent neurologic damage. A ray of hope is offered by the results of Lincoln and her associates.[7] They obtained clinical arrest in 6 of 7 patients treated with a combination of streptomycin and promizole® (4,2′-diaminophenyl-5′-thiazolyl sulfone). Prolonged follow-up on these patients as well as further studies on combinations of streptomycin and various antituberculous chemicals will be welcome.

TABLE 2.—*Suggested Treatment for Various Types of Bacterial Meningitis*

Etiology	Sulfonamide Drug	Penicillin	Streptomycin
Gram-neg. cocci Meningococci Gonococci	Sulfadiazine or sulfamerazine systemically	In fulminating infections as for gram-pos. cocci	None
Gram-pos. cocci Pneumococci Beta streptococci Staphylococci	None	1,000,000 units intramuscularly every 2 hours; in comatose patients initial intrathecal injection of 20,000 units	None
Gram-neg. rods H. influenzae * E. coli Ps. aeruginosa and others	Sulfadiazine or sulfamerazine systemically	None	Systemically, 3 Gm./day to adults; 1.5 Gm./day to infants; intrathecally 50 mg./day to adults and 25 mg./day to young children
Tubercle bacillus	None	None	Systemically, 9 mg./Kg./day (maximum 2 Gm.); intrathecally, 1 mg./Kg. (maximum 50 mg.)/day; then on alternate days

* In cases of severe disease, specific serum in doses of 100 to 200 mg. of antibody nitrogen.

Patients with tuberculous meningitis should be treated as early in the course of the disease as possible with intramuscular doses of 9 mg. per kilogram of body weight per day, up to a maximum of 2 Gm., at six hour intervals. Intrathecal doses of 1 mg. per kilogram, up to a maximum of 50 mg., are also given, at first at daily intervals and after two weeks on alternate days. It is usually recommended that treatment be continued for four months, but it is doubtful whether streptomycin is of any value after six to eight weeks. The spinal fluid leukocyte count and protein content are no criteria of recovery. More reliable are the absence of organisms in smear and culture and a return of dextrose content to normal.

LOCALIZED INFECTIONS OF THE CENTRAL NERVOUS SYSTEM

The same procedures should be used in the treatment of abscesses as are used in meningitis. The causative organism should be determined and the proper antibiotic or sulfonamide compound should be used. Surgical drainage with local instillation of the proper antibiotic should be employed where advisable.

SUMMARY

The treatment advocated in the various types of meningitis caused by bacteria is outlined in table 2. Meningitis caused by gram-negative cocci is best treated with sulfonamide compounds, penicillin being used as an adjuvant in cases of severe disease. When gram-positive cocci are the cause, penicillin should be given in massive doses systemically. Comatose patients may receive one intrathecal dose at the start of treatment. In meningitis caused by gram-negative rods, sulfonamide compounds should be given in combination with streptomycin. In severe H. influenzae infections, specific serum should be given also. In tuberculous meningitis, systemic and intrathecal administration of streptomycin should be continued for several weeks or months.

ABSTRACT OF DISCUSSION

Dr. Paul S. Rhoads, Chicago: Dr. Dowling emphasizes two procedures which I am sure are not in general use. One is the administration of maintenance doses of sulfonamide drugs in comatose patients by stomach tube after an initial 6.0 Gm. dose of the sodium salt intravenously. I am sure the method accomplishes what he is after—the avoidance of fluctuations in the blood level. Since comatose patients require almost constant administration of fluids intravenously we usually continue the maintenance dose by adding 1.0 Gm. of sodium sulfadiazine to them every four hours or 2.0 Gm. of sodium sulfamerazine every eight hours—and have found that fluctuations in blood level on this schedule are not violent. He spoke of the use of a new sulfonamide drug prepared by the Hoffman-LaRoche Company which is more soluble in the urine than the ones now in general use, and which is not irritating when given intramuscularly as the lithium salt. We have used this drug as the sole antibacterial therapy in 8 cases of meningococcic meningitis and in combination with penicillin in 3 others—and all the patients recovered. Probably when this or other sulfonamide drugs which can safely be injected into the muscle in 20 to 40 per cent solution come into general use the need for administration by stomach tube will be over. The other new departure emphasized by Dr. Dowling is the intramuscular injection of 1,000,000 units of penicillin every two hours in pneumococcic meningitis and certain other severe infections of the central nervous system. By this technic he is able to produce an effective level of penicillin in the spinal fluid in most cases. The results—even without the combined use of sulfonamide compounds—compare favorably with those in any large series of patients with pneumococcus meningitis yet reported. Whether the advantages of this method—which is expensive and requires twelve intramuscular injections each twenty-four hours —outweigh the possible danger of a single intrathecal injection of 10,000 to 20,000 units of penicillin each twenty-four hours I am not prepared to say. In our experience there have been no difficulties with intrathecal administration in this dosage, and we have always found a satisfactory level of penicillin in the spinal fluid twenty-four hours later. I am not quite ready to abandon daily intrathecal injections in patients with a poor prognosis in favor of this method, although I am heartily in favor of larger parenteral penicillin dosage than we have used in the past. In the treatment of meningitis due to H. influenzae I agree that streptomycin is probably the single most effective agent.

Dr. Wesley W. Spink, Minneapolis: In the face of standardized recommendations for treating pneumococcic meningitis, Dr. Dowling and his co-workers are to be commended for withholding the intrathecal injection of penicillin in a significant group of patients. They have shown that the parenteral administration of large doses of penicillin will result in the drug's penetrating the blood-brain barrier and appearing in sizable quantities in the cerebrospinal fluid. This applies to the patient with inflamed meninges, but not to normal persons. I agree with Dr. Dowling that sulfadiazine or sulfamerazine is the drug of choice in the treatment of meningococcic meningitis and that in this infection intrathecal therapy is not necessary. Our group has been interested in the problem as to whether it is mandatory that solutions of penicillin be administered intrathecally for pneumococcic meningitis, as well as being given parenterally. We have not been particularly concerned about the harmful effects of intrathecally administered penicillin, and have observed no undesirable reactions following this procedure. Perhaps this is due to the fact that no more than 20,000 units of penicillin have been injected in 10 cc. of isotonic sodium chloride solution. Until the present time, we have insisted on the intrathecal administration of penicillin as a part of the routine treatment of pneumococcic and staphylococcic meningitis. Recent investigations in our laboratory tend to confirm the conclusion of Dr. Dowling that large amounts of parenterally administered penicillin will result in good concentrations of the antibiotic in the cerebrospinal fluid. In accordance with the suggestion of King and his group at Mount Sinai Hospital in New York, 1,000,000 units of the crystalline sodium salt of penicillin G in 5 cc. of distilled water has been rapidly injected intravenously into each of several human subjects. This procedure will result in blood levels of over 100 units per cubic centimeter. Thirty minutes later one-half this amount is present. In persons with normal meninges, the concentration of penicillin in the cerebrospinal fluid did not exceed 0.5 unit per cubic centimeter at any time, whereas in patients having inflamed meninges, levels up to 8 units per cubic centimeter were attained in the cerebrospinal fluid. Such concentrations would appear to be adequate for eradicating pneumococci from the fluid. Most clinicians are now agreed that in the treatment of tuberculous meningitis streptomycin should be injected into the subarachnoid space as well as administered intramuscularly. There is considerable doubt as to whether it is advisable to introduce more than 25 mg. of streptomycin at any one time, since amounts greater than this have provoked irritation of the meninges.

Dr. William P. Boger, Philadelphia: Dr. Spink indicates that he has confirmed the passage of penicillin into the cerebrospinal fluid, but made the remark that it is difficult to pass a normal blood brain barrier. Recently, we reexamined this point and found that significant amounts of penicillin are found in the cerebrospinal fluid in the majority of normal patients, if 100,000 units of penicillin are administered intramuscularly at three hour intervals. Having demonstrated that in 20 of 25 patients this was true, the rapidity of passage of penicillin into the cerebrospinal fluid was studied. We were able to demonstrate that a single intravenous injection of 500,000 units of penicillin resulted in the appearance of penicillin in the spinal fluid within two hours. The amounts of penicillin in the cerebrospinal fluid were doubled when carinamide was administered intravenously with the same dose of penicillin, and when penicillin and carinamide were given together no case failed to show penicillin in the spinal fluid. This was a controlled series of cases, the same patients being studied with penicillin alone and then later when penicillin was given in conjunction with carinamide. These findings were applied to the treatment of purulent meningitis. Within two hours following a single intravenous dose of 500,000 units of penicillin as much as 2 and 8 whole units of penicillin per cubic centimeter of cerebrospinal fluid have been observed. Since the samples were taken from the lumbar region it is implied from what is known of the formation of cerebrospinal fluid that within two hours penicillin had diffused throughout the subarachnoid space. Certainly, whole units of penicillin are bactericidal for pneumococci and, although we may be inclined to administer the antibiotic intrathecally, it would appear unnecessary in view of these findings.

Dr. W. James Gardner, Cleveland: It is not unfortunate, but it is a fact that the appearance of penicillin on the medical horizon somewhat discouraged the further investigation of the effectiveness of the sulfonamide compounds. A fact which Dr. Dowling did not mention is that it has been found by laboratory work that the administration of urea enhances tremendously the effectiveness of the sulfonamide compounds. That is in vitro as well as in vivo, locally as well as systemically. The action of urea, and the method by which urea enhances the effectiveness of the sulfonamide compounds, is that it inhibits the normal inhibitors of sulfonamide compounds, and increases the solubility of the sulfonamides. It increases their ability to penetrate tissues and it may lower the blood brain barrier to the passage of sulfonamide compounds.

Dr. Percival Bailey, Chicago: After these infections have been cured, the rest of humanity that are left are gravitating to the hands of the neurologist. In my experience, I have seen several cases in which I have been convinced that intrathecal therapy increased these disabilities. I was therefore greatly pleased when Dr. Dowling stated that he no longer needed to put penicillin into the spinal fluid. I look forward to the day when he will cease putting streptomycin into the spinal column also. I have never believed that treatment was helped by putting the drug into the spinal canal.

Dr. Harry F. Dowling, Washington, D. C.: With regard to Dr. Spink's findings on the penetration into the cerebrospinal fluid, we also found that in normal patients the penetration is not as good as in those with meningitis, but with the dose that we use we always obtain in a significant concentration after eight hours. We used this dose in a large enough series of patients to prove statistically that we had a method of treatment which was worth while. It is true, as Dr. Spink says, that when no more than 20,000 units is given at one time, we seldom get any neurologic complications, but there are cases reported in the literature in which these have occurred on a dose of 20,000 units. Not only that, I wish I could have had time to show you the rapid drop in temperature which occurred in the recovered patients who received this systemic penicillin as compared with those patients who received the combination. Also, pleocytosis disappeared much more rapidly in the recovered patients who received the systemic penicillin alone, as compared with those who received the combination. I think Dr. Spink has a point that we do not know yet what to recommend in staphylococcic meningitis. It is probably best to use the orthodox treatment of combined injections until we can prove that intrathecal injections are not needed. I was very interested in Dr. Gardner's remarks on urea. I feel that that is something worth investigating. We have not used it clinically. Dr. Boger's discussion pointed up the one fact that if we use some other method, particularly in his case carinamide, we may be able to get the same results that we got with our dose. We did not employ carinamide, although that seemed a feasible thing to do, because, as I say, we wanted to get enough patients who had been treated in exactly the same way to prove whether this method was worth while. I think in the future we will try some method similar to that mentioned by Dr. Boger. With regard to Dr. Bailey's statement on the use of streptomycin intrathecally, I know that there is a point. I wish I felt free to do without it, but the experience of the medical research council of England seems to show that it is necessary to use streptomycin intrathecally. Here we cannot raise the systemic dose, ad libitum, as we can with penicillin, in order to get penetration.

DANGER OF DICUMAROL® TREATMENT IN PREGNANCY

ALFRED P. KRAUS, M.D.
SAMUEL PERLOW, M.D.
and
KARL SINGER, M.D.
Chicago

The increasing use of dicumarol® in the prevention and treatment of thromboembolic phenomena brings up the clinically significant question whether this drug, when given to a pregnant woman, has any deleterious effects on the growth and development of the fetus. Schofield[1] in 1924 noticed that newborn calves appeared to be much more sensitive to toxic sweet clover hay than mature animals did. Roderick and Schalk[2] recorded similar experiences. Quick[3] gave dicumarol® to 2 dogs during their last week of pregnancy; he observed that the prothrombin levels of the newborn pups were definitely reduced (less than 1 per cent of normal), in spite of the fact that the prothrombin levels of the mothers were maintained well within a "safe" range. The pups also showed a decided tendency toward bleeding, and none of them survived, unless vitamin K was given. Quick concluded that the administration of dicumarol® is contraindicated during pregnancy. Our investigation was undertaken to observe the influence of dicumarol® not only on the newborn but also on the intrauterine growth and development of the fetus. The rabbit was selected for these experiments because of its short gestation period.

MATERIAL AND METHODS

Female rabbits weighing 3 to 6 Kg. were used in the experiments. The animals were kept in separate cages and fed only purina® rabbit chow and water. Determinations of the prothrombin time were performed by Quick's one stage method. It was realized that this test does not measure the true level of prothrombin alone but also indicates the interdependent actions of several components involved in the clotting process, namely, prothrombin, the fifth factor[4] (Ac-globulin[5] and labile factor[6]), thromboplastin and calcium, when, of course, a sufficient quantity of fibrinogen is present. The one stage method was selected because of its widespread clinical use, thus enhancing the interpretation of the experimental findings. For this reason also, the lower limit of the "safe" range was arbitrarily set at 10 per cent of normal, as it is commonly done in the dicumarol® therapy of human beings.[7]

Batches of thromboplastin were prepared from several rabbit brains according to Quick's acetone dehydration method.[8] A saline suspension was then made immediately, kept at 50 C. for fifteen minutes with constant stirring, centrifuged slowly for five minutes and stored in the dry ice box in stoppered vials

in aliquots of 1.5 cc.[9] Such a batch of thromboplastin retained its full potency for months and allowed direct comparison of the prothrombin times from day to day. Frequent prothrombin determinations on normal rabbits consistently gave values between six and seven seconds. Proper dilution curves were also performed at frequent intervals.

Blood for the prothrombin time determinations was drawn by means of heart puncture in the control animals and by ear vein puncture in dicumarolized animals. The ear vein puncture was used in preference to the heart puncture because of the danger of fatal hematopericardium in dicumarolized animals.[10] The blood of the newborn rabbits was drawn by heart puncture. The babies usually did not survive the heart puncture for more than one day. Therefore, the prothrombin time was not determined in all the litter mates, but in a representative group only, in order to permit the study of survival rate of the newborn rabbits.

Dicumarolization was accomplished by placing the appropriate quantity of pure dicumarol® powder [11] into no. 5 gelatin capsules. These capsules were put into one end of a short piece of rubber tubing. The rabbit's mouth was held open by a gag, the tube inserted deeply into the pharynx and the capsules flushed out of the tube with 2 to 3 cc. of water by means of a syringe.[12] This procedure prevented the regurgitation of the capsule. Although the oral application of dicumarol® introduces the conceivable factor of variable absorption into the experimental conditions, we found that this type of administration gave satisfactory results. The oral route also seemed preferable because it was thought that daily injections into the ear veins might increase the danger of undesirable damage to these vessels, which were already so often used for obtaining blood for the prothrombin determinations. Intraperitoneal administration seemed inadvisable because of the possible interference with the pregnant state of the animals.

Prothrombin Times of Pregnant Rabbits Receiving No Dicumarol®

Animal	Prothrombin Times							
	1		2		3		4	
	Sec.	%	Sec.	%	Sec.	%	Sec.	%
Mother	6.4	100	7.0	100	7.0	100	6.4	100
Baby 1	7.8	75	7.4	87	8.0	60	6.4	100
Baby 2	7.0	75	7.4	85	8.6	45	6.4	100
Baby 3	...	...	...	...	8.6	45	6.6	95

RESULTS

I. *Controls.*—Four pregnant rabbits were used as controls and did not receive any dicumarol.® The results are compiled in the table.

The somewhat lower prothrombin levels demonstrated in the babies of mothers no. 1 and no. 2 and the even more depressed levels of the babies of mother no. 3 might be explained by the drop of prothrombin value in newborn rabbits during the first twenty-four hours as determined with the one stage method.[8] This phenomenon has been described by numerous investigators.[18] These babies were born during the night, and the determinations of the prothrombin time were not performed until the next morning, corresponding to an interval of eight to twelve hours. The babies of rabbit no. 4 were examined within one hour after birth and consequently showed practically normal prothrombin values.

II. *Effect of "Unsafe" Doses of Dicumarol.®*—Four rabbits received doses of dicumarol® sufficient to cause depression of the prothrombin level to less than 10 per cent of normal. These low levels were never maintained for more than a few days. Whenever the prothrombin level reached such low values, the drug was withheld. However, no vitamin K was given at any time.

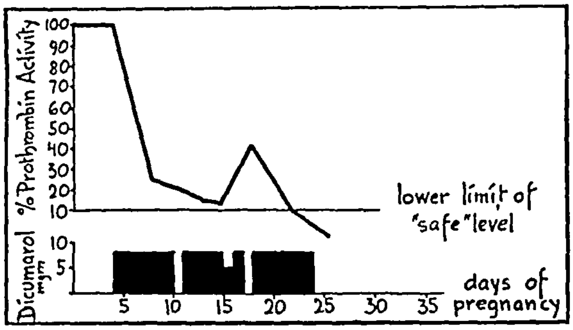

Fig. 1.—Graph showing effect of "unsafe" doses of dicumarol® on prothrombin levels of rabbit no. 5. Seven macerated fetuses were found in utero, weighing 17 to 21.5 Gm., which had been dead for at least several days prior to the death of the mother.

Rabbit no. 5 was started on 8 mg. of dicumarol® on the fifth day of pregnancy. The prothrombin level fell to 25 per cent by the eighth day and thereafter was maintained between 10 and 25 per cent, with the exception of the eighteenth day, when it rose to 40 per cent. On a continued daily dose of 8 mg. of dicumarol,® the prothrombin level fell to less than 1 per cent on the twenty-fifth day; the rabbit died on the twenty-sixth day, two days after discontinuation of the dicumarol® administration. Blood was observed in the nostrils and vaginal bleeding had started. Postmortem examination disclosed multiple hemorrhages into the lungs. The uterus contained about 100 cc. of nonclotted blood. In the uterus were found seven baby rabbits, weighing between 17.0 and 21.5 Gm., as compared with normal weights of 30 to 60 Gm. All fetuses were macerated and showed evidence of having been dead several days prior to the death of the mother.

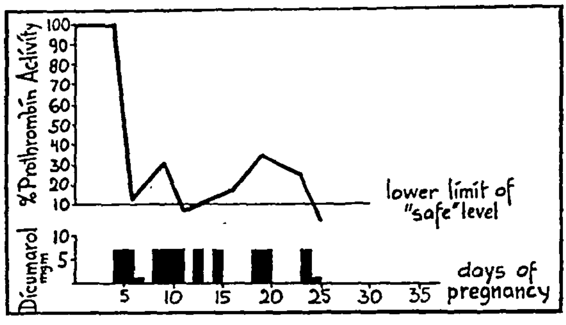

Fig. 2.—Graph showing effect of "unsafe" doses of dicumarol® on prothrombin levels of rabbit no. 6. One baby (weight, 25 Gm.) was born dead. Eight macerated fetuses, weighing 10 to 40 Gm., were found in utero.

Rabbit no. 6 was started on 7 mg. of dicumarol® on the fifth day of pregnancy. By the sixth day the prothrombin level had fallen to 12 per cent of normal. Only 1 mg. of dicumarol® was given on that day and the drug was withheld the next day. By the ninth day a prothrombin level of 30 per cent was found. On the eleventh day the prothrombin level again had fallen to only 6 per cent of normal. Thereafter, prothrombin was kept above 10 per cent, at one time reaching 35 per cent. However, on the twenty-fifth day a dangerously low level was present (2 per cent). Dicumarol® was again discontinued, and the rabbit died on the twenty-ninth day, after delivering one dead fetus weighing 25 Gm. There was considerable blood in the cage. On postmortem examination the uterus contained about 40 cc. of liquid and some clotted blood. Eight infant rabbits were found in utero. Two of these were very small, weighing only 10 and 12 Gm., respectively, and consisting mainly of placental tissue with some unrecognizable tissue attached to it. The other 6 babies weighed between 30 and 40 Gm. and were relatively well developed. From the discrepancy in weight and development of the infant rabbits, it may be surmised that the two immature ones died during the first episode of dicumarol® poisoning on about the eleventh day of pregnancy, while the remainder survived until about the twenty-fourth day of pregnancy.

A. **115:** 1416 (Oct. 26) 1940.

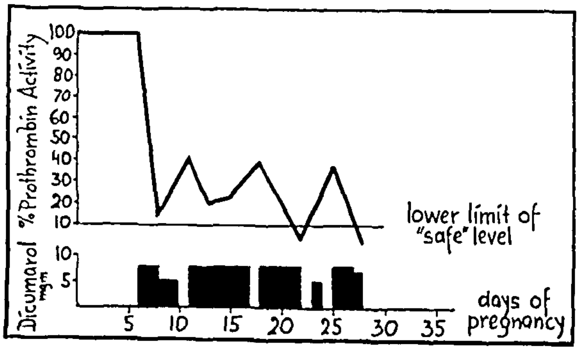

Fig. 3.—Graph showing effect of "unsafe" doses of dicumarol® on prothrombin levels of rabbit no. 7. Four babies (weight, 30 to 44.5 Gm.) were born dead; 2 fetuses were found in utero (weight, 1 and 36.5 Gm., respectively). All showed severe maceration.

Rabbit no. 7 was started on 8 mg. of dicumarol® on the sixth day of pregnancy. It was maintained on prothrombin levels between 10 and 40 per cent of normal until the twenty-second day of pregnancy, when an "unsafe" level of 3 per cent was reached. Dicumarol® was discontinued for one day; the next day only 5 mg. was given, and the day after, dicumarol® again was omitted. On resumption of administration of the drug, the prothrombin level again dropped to 1 per cent on the twenty-eighth day, and the rabbit died on the thirtieth day, after delivering four dead babies weighing between 30 and 44.5 Gm. The rabbit lost a considerable amount of blood during the delivery. Three of the four baby rabbits were macerated. On postmortem examination two infant rabbits were found in the uterus, one weighing 36.5 Gm. and one 1 Gm. The uterus contained 20 cc. of nonclotted blood and a blood clot measuring 2 by 10 cm. The rabbit also showed some retroperitoneal hemorrhage and bleeding into the wall of the colon.

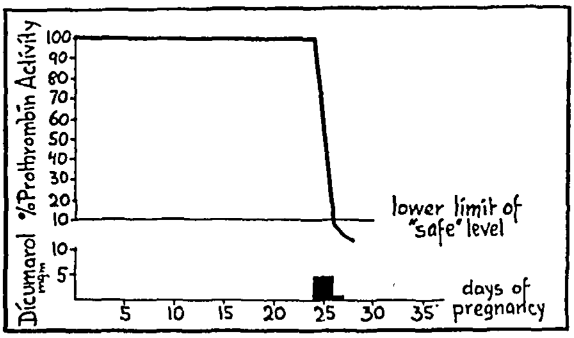

Fig. 4.—Graph showing effect of "unsafe" doses of dicumarol® on prothrombin levels of rabbit no. 8. Two babies were born dead and 7 alive (weight, 40 to 60 Gm.).

Rabbit no. 8 was not started on dicumarol® until the twenty-fourth day of pregnancy. A total dose of only 10.5 mg. of dicumarol® was given. In spite of this small dose, the prothrombin level fell to 2 per cent of normal on the twenty-eighth day and the rabbit died on the thirty-first day, after delivering two dead and seven live babies. The prothrombin level of two of these infant rabbits was 37 per cent of normal immediately after birth. This was four days after dicumarol® had been discontinued in the mother.

These experiments demonstrate that none of the mother rabbits showing a fall of the prothrombin level below 10 per cent of normal at one time or another during pregnancy survived. None of the fetuses survived up to the time of delivery except those of rabbit no. 8, which received dicumarol® only during the last week of the gestation period. The fetuses were small, with conspicuous maceration of the skin and decomposition of the tissues. These fetal changes resulted in spite of the fact that the "unsafe" levels of prothrombin (below 10 per cent) were not maintained for more than two to three days. There were no signs of manifest bleeding in the live babies, which after delivery showed normal development.

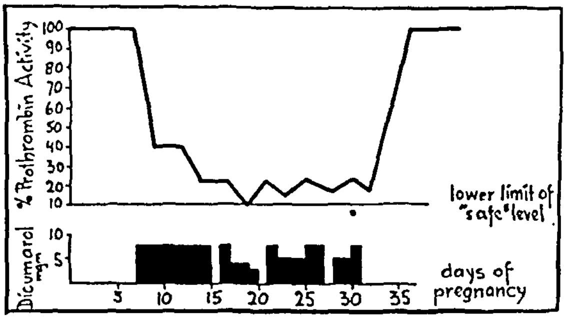

Fig. 5.—Graph showing effect of "safe" doses of dicumarol® on prothrombin level of rabbit no. 9. Two severely macerated babies (weight, 18 and 20 Gm., respectively) were born dead. Four were born alive (weight, 55 to 64 Gm.) with signs of hemorrhagic tendency.

III. *Effect of "Safe" Levels of Dicumarol.®*—Four pregnant rabbits were kept at a "safe" level of dicumarol® administration during their gestation period.

Rabbit no. 9 was started on 8 mg. of dicumarol® per day on the seventh day of gestation. The prothrombin level fell to 40 per cent on the ninth day and to 22 per cent on the fourteenth day and thereafter was maintained between 10 and 25 per cent by means of 5 to 8 mg. of the drug for the remainder of the pregnancy. It delivered six babies on the thirty-first day of pregnancy. Two of these were born dead, weighing only 18 and 20 Gm., respectively. They were badly macerated, indicating early intrauterine death. Two infant rabbits died within thirty minutes after birth; they showed widespread hemorrhages and weighed 55 and 62 Gm., respectively. The fifth baby rabbit weighed 64 Gm., had a prothrombin level of 2 per cent (that of the mother was 18 per cent) and was bleeding from the nostrils. The last baby weighed

57 Gm. with a prothrombin level of 5 per cent of normal. Both these babies died within thirty-six hours.

Rabbit no. 10 was given 8 mg. of dicumarol® per day, starting on the sixth day of pregnancy. The prothrombin level showed considerable fluctuation, reaching 36 per cent on the fifteenth day, 90 per cent on the eighteenth day, 20 per cent on the twenty-eighth day, 50 per cent on the thirtieth day and, finally, 18 per cent on the day of delivery. Thirteen live baby rabbits were born on the thirty-second day of pregnancy. In a representative group of four infant rabbits, including the animals of the lowest and highest weight, two with and two without outward signs of hemorrhage, the prothrombin levels were all demonstrated to be below 1 per cent of normal. Two of the other babies also showed evidence of hemorrhage. Eight babies were dead one day after delivery, including the four who underwent heart puncture. All baby rabbits died within five days after delivery. The mother did not lose an excessive amount of blood during delivery and remained healthy.

Rabbit no. 11 was started on 8 mg. of dicumarol® on the seventeenth day of pregnancy. The prothrombin level reached 23 per cent on the twenty-first day and then remained between this level and 10 per cent up to the day of delivery. The rabbit gave birth to eleven babies on the thirty-first day; one of them was born dead, weighed 33 Gm. and showed some signs of maceration. The prothrombin level in five of the live infant rabbits on the day of delivery was less than 1 per cent. One baby had a prothrombin level of 2 per cent. The day after delivery one baby rabbit had a prothrombin level of 18 per cent and another one of 25 per cent. The two infant rabbits which were not subjected to heart puncture died the day after delivery, and all babies were dead by the fifth day.

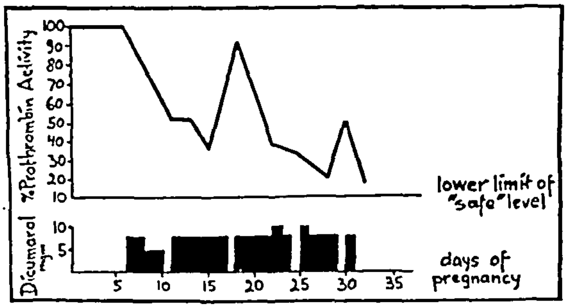

Fig. 6.—Graph showing effect of "safe" doses of dicumarol® on prothrombin levels of rabbit no. 10. Thirteen live babies (weight 24 to 55 Gm.) were born with signs of hemorrhagic tendency.

Rabbit no. 12 began to receive dicumarol® (7 mg. daily) on the fourth day of pregnancy. The prothrombin level fell to 50 per cent on the sixth day and to 40 per cent on the eleventh day. Then the level rose to 80 per cent on the sixteenth day and fell to 29 per cent on the nineteenth day. The animal started vaginal bleeding on the twenty-first day of pregnancy and passed some tissue and blood clots. No further dicumarol® was given; however, the rabbit died on the twenty-sixth day. The uterus contained eleven macerated, bady decomposed fetuses, measuring 1 to 3 cm. in length, and some bloody fluid. The uterine wall showed hemorrhagic areas. On microscopic examinations, placental tissue could be recognized with certainty; however, the fetuses themselves were too badly decomposed to allow recognition of any of the organs. No other abnormalities were observed in the mother.

These experiments show quite clearly the damaging effect of even "safe" doses of dicumarol® on the embryos. While 3 of the 4 mother rabbits survived after delivery and did not have any excessive intrapartum and postpartum bleeding, the babies sustained an extreme depression of their prothrombin levels at birth. The newborn rabbits exhibited a pronounced hemorrhagic tendency, and their longest survival time was five days. A few fetuses died before delivery.

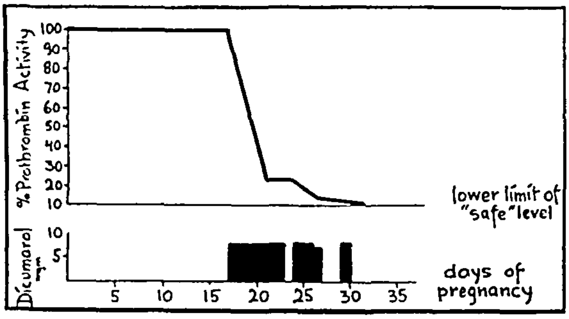

Fig. 7.—Graph showing effect of "safe" doses of dicumarol® on prothrombin levels of rabbit no. 11. One macerated baby was born dead (weight, 33 Gm.). Ten were born alive (weight, 34 to 51.5 Gm.) with signs of hemorrhagic tendency.

COMMENT

The occurrence of thrombosis in pregnant women brought up the question of the advisability of dicumarol® therapy in this condition. A search through the literature did not reveal any experimental studies of this clinically significant problem, with the exception of the animal experiments by Quick.[3] Neuhof [7a] stated that dicumarol® is contraindicated during pregnancy and based this statement on the belief that the drug will cause excessive hemorrhage during and after delivery. Von Sydow [14] observed 1 patient who received the drug during the last month of pregnancy. The newborn infant showed severe subcutaneous hemorrhages, and treatment with vitamin K did not increase the prothrombin level until six days after birth.

Our experiments seem to demonstrate that dicumarol® passes the placental barrier. Three of the 4 animals kept on "safe" prothrombin levels during the administration of the drug delivered in a normal manner and showed no evidence of excessive intrapartum and postpartum bleeding. The fourth aborted on the twenty-first day and died five days later. However,

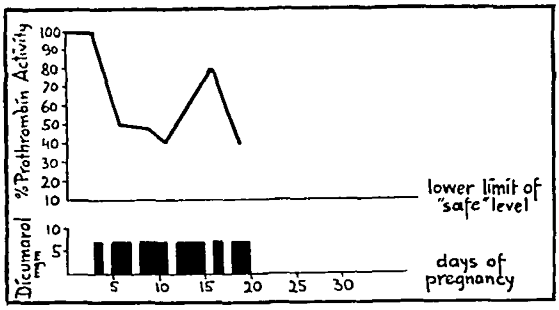

Fig. 8.—Graph showing effect of "safe" doses of dicumarol® on prothrombin levels of rabbit no. 12. Eleven macerated fetuses were found in utero.

[14] von Sydow, G.: Hypoprothrombinemia and Cerebral Injury in Infant After Dicumarol Treatment of Mother, Nord. med. 34: 1171, 1947; abstracted in Videbaek, A.: A Review of the Scandinavian Literature on Hematology from the Years 1946 and 1947, Acta Haemat. 1: 126, 1948.

We have had 1 fatality (case 22) attributable to dicumarol® among 273 patients in whom we have supervised anticoagulant therapy.[8a] This patient, a 43 year old white woman, was referred to the University Hospital for evaluation of her hypertension. There was a history of a cerebrovascular accident about ten months before admission. During the course of her studies, anticoagulant therapy was undertaken because of an acute occlusion of a retinal artery; heparin, received initially, was supplemented by dicumarol.® Dicumarol® was discontinued on the eleventh day of treatment after a total of 2.0 Gm. had been administered. The prothrombin level (Quick procedure) had been satisfactorily controlled between 30 to 20 per cent of normal concentration until the thirteenth day, when it suddenly dropped to less than 5 per cent of normal concentration. At this time the patient complained of dizziness and frontal headache; shortly thereafter she lapsed into coma with signs of a left hemiplegia and meningeal irritation. Seventy-two milligrams of vitamin K (hykinone®) were given intravenously; death occurred about four hours after the onset of symptoms. Permission for an autopsy was not obtained. Despite the lack of objective bleeding, a cerebrovascular accident is assumed to have been the cause of death. We have felt that the association of this accident with the excessive hypoprothrombinemia may well have been more than coincidental.

The absolute necessity of reliable laboratory facilities to guide the administration of dicumarol® is clearly illustrated in case 21. The patient, who suffered from thrombophlebitis and pulmonary emboli, died in a state of hemorrhagic diatheses during dicumarol® therapy. An average dose of 240 mg. of dicumarol® administered daily for fourteen days had failed to increase the prothrombin to the desired therapeutic level, as measured by the technic employing Russell viper venom as thromboplastin. Subsequent investigation disclosed the method insensitive to decided changes in prothrombin levels as evident when tested by the Quick procedure.

Particularly unfortunate have been those fatalities occurring when dicumarol® has been administered to patients without the benefit of prothrombin determinations. Fahraeus [9] (as noted by Thorsen [4]) reported a death from gastric bleeding (case 4) after 250 mg. of dicumarol® had been given daily for ten days without estimation of the prothrombin time. Smith,[10] commenting on the inadvisability of use of the drug when laboratory facilities are unavailable, mentioned a "disastrous result in one case when a dose of 250 mg. of dicumarol raised the prothrombin time to 9 minutes." Shlevin and Lederer (case 8) reported [11] the first case with postmortem observations of uncontrollable hemorrhage after dicumarol® therapy. This patient, prior to coming into their hands, had received 100 mg. of dicumarol® daily for twenty-one days for a retinal vein thrombosis; therapy was uncontrolled by prothrombin determinations. We have recently seen a similar case (case 23) in which large doses of dicumarol® had been administered daily for about thirty-seven days with no laboratory control.

REPORT OF A CASE

A 36 year old white woman was first admitted to the University Hospital as an emergency patient at 2 p. m. on Dec. 29, 1947. According to the accompanying letter from the referring physician, the patient had complained of violent headaches and pain in the shoulders, neck and back. These symptoms were associated with extreme weakness, nausea, lower abdominal cramps, hemoptysis and vaginal bleeding. The past history revealed that she had had pulmonary tuberculosis for which she had received sanatorium care for eight months in 1928; three months prior to the present illness she had had a normal chest roentgenogram and a negative reaction to a tuberculin test. An appendectomy had been performed in 1945. The family history was irrelevant.

According to her husband, from whom the details of the present illness were obtained, dicumarol® had been administered because of the recent onset of pain and swelling of both legs. Treatment with the drug was started on Nov. 20, 1947 and continued until December 27 in a dosage thought to be 300 mg. daily. In this period a total of about 11.1 Gm. is estimated to have been ingested; the prescription had been refilled on three different occasions, despite the fact that the condition of her legs had improved. She had also received orally an unknown amount of penicillin; no information was available concerning the use of sulfonamide drugs. In this period she was up and about the home; no laboratory studies were carried out. Nothing untoward took place until about December 22, when there was the onset of blood-streaked sputum. Two days later, because of nausea and vomiting, dicumarol® had been withheld and the patient was put to bed. On December 27, she complained of a severe and progressive headache. The day before admission the patient became irrational, bleeding began from the mouth and vagina, and there was gross hematuria. There had been no epistaxis.

On admission to the Medical Service, the patient was obviously acutely and critically ill, being semicomatose and disoriented. Though well developed and nourished, she was in a state of peripheral vascular collapse, with the blood pressure at 80 systolic and 60 diastolic, the pulse rate 130, the respirations 15 per minute and the temperature 98.6 F. There was a small amount of blood-streaked sputum and moderate bright red vaginal bleeding. Submucosal ecchymoses were observed on the tongue, gums and cheeks and in the pharynx. There were ecchymoses on the extremities, which measured up to 3 cm. in diameter; petechiae were not observed; the result of the tourniquet test was negative. Bleeding into the fundi was not seen. A systolic murmur was heard over the entire precordium. The neurologic examination revealed fixation and constriction of the left pupil, ptosis of the right eyelid and a left-sided facial paralysis with deviation of the tongue to the left. There was nuchal rigidity. Kernig's and Brudzinski's signs were positive. There was weakness of the left arm and leg; the left achilles reflex was hyperactive; ankle clonus and the Babinski sign were present bilaterally. The patient was unresponsive to light, touch or vibration. Deep pain produced a withdrawal reaction.

It was possible to do only the more urgent laboratory studies. The urine contained gross blood. Blood hemoglobin measured 9 Gm. (Sahli). The bleeding time (Ivy method) was prolonged to 7 minutes; the clotting time (Lee and White method) was prolonged to 48 minutes; clot retraction was decidedly deficient at the end of 2 hours. The prothrombin time (Quick procedure) was prolonged to 500 seconds in one determination and 800 seconds in another, with the normal control time of 16 seconds. The amount of prothrombin was so depleted that expression in terms of percentage of concentration, from the standard dilution curve, was impossible. The result of the postmortem Kahn serologic test was positive.

Heroic efforts were made to control the inevitable course of the hemorrhagic diatheses. With 1,000 cc. of blood and 1,500 cc. of 5 per cent dextrose, the peripheral vascular collapse was temporarily controlled, the blood pressure eventually rising to 130 systolic and 78 diastolic. Seventy-two milligrams of vitamin K (hykinone®) was administered intravenously every three hours, a total of 222 mg. being received in fourteen hours. Despite some initial improvement, the patient never regained consciousness; restraints were required. Eight hours after her admission, the respirations became Cheyne-Stokes in character. Death occurred fifteen hours after her admission to the hospital, and three days after the dicumarol® therapy had been discontinued. The prothrombin time of blood obtained at autopsy (four hours after death) was 85 seconds, as compared with the normal control time of 16 seconds. The prothrombin concentration was estimated to have been less than 5 per cent of normal.

[8a] Since completion of this report a second fatality due to dicumarol has occurred in the University Hospital. This patient, a 79 year old woman, likewise had severe hypertension and had sustained cerebrovascular accidents several months prior to admission. Prophylactic dicumarol, instituted subsequent to a femoral neck fracture, was associated with a sudden drop in prothrombin to a low level coincident with which the patient sustained a fatal cerebral hemorrhage. An autopsy was not permitted. The occurrence of these two fatalities stresses the hazard of administering dicumarol to patients with severe hypertension, particularly if there is a past history of cerebrovascular accidents.

Postmortem Examination.—Gross Pathologic Observations: The pertinent gross pathologic observations were as follows: The head and neck were essentially normal, except for the presence of considerable serosanguineous exudate in the oral pharynx. There were multiple puncture wounds on the arms, antecubital fossae and buttocks, in association with some of which there were diffuse hematomas. There was an old lower abdominal midline scar.

The brain weighed 1,160 Gm. The meningeal vessels were congested. Beneath the right inner meninges was a diffuse hematoma over the entire right hemisphere; the left meninges were congested. The right hemisphere was swollen and edematous; sulci were narrowed; gyri flattened. There was a lemon-sized hemorrhagic softened necrotic lesion in the right parietotemporal region near the external cortical surface and ventricle. The left hemisphere was edematous and congested and contained multiple petechial hemorrhages throughout. The ependymal surface of the right and left lateral ventricles showed congestion. The choroid plexus was hemorrhagic and cystic. Examination of the lumbar part of the spinal cord revealed a diffuse hematoma beneath the pia-arachnoid.

The pleural cavities contained no excess free fluid and were obliterated bilaterally along the posterior gutters by dense fibrous adhesions. The left lung weighed 550 Gm. The cut surface disclosed acute passive congestion. The right lung weighed 600 Gm.; its gross appearance was comparable with the left. There was severe congestion of the mucosa of the trachea, bronchi and esophagus; the bronchi contained a moderate amount of serosanguineous exudate. The thoracic and abdominal aorta revealed slight atherosclerosis of the intima.

There were 40 cc. of serosanguineous fluid in the pericardial sac. The heart weighed 240 Gm. The thickness of the left and right ventricular walls was normal, with normal epicardial and endocardial surfaces. A few petechial hemorrhages were present in the right ventricle and right atrium; no thrombi were found. The dimensions of the mitral, tricuspid, pulmonary and aortic valves were normal. A few yellow nodules were present on the leaflets of the mitral and tricuspid valves and on the free margins of the aortic cusps. A diffuse hematoma was present in the atrial wall at the entrance of the superior vena cava. The coronary arteries revealed slight atherosclerotic changes.

The abdominal cavity contained approximately 100 cc. of fluid blood distributed over loops of large and small intestines; fibrous adhesions were present. The peritoneum, which was pinkish purple, contained multiple petechial hemorrhages throughout. The spleen weighed 100 Gm.; the cut surface showed a purplish red splenic pulp with well marked malpighian corpuscles; there was no infarction. The mucosa of the large and small intestines was congested but not hemorrhagic. The appendix was absent. Serosal hemorrhages were present in the stomach. The pancreas weighed 100 Gm. and was free of hemorrhage. The liver measured 6.5 cm. below the ensiform and 2 cm. below the right costal margin; its weight was 1,540 Gm. The external, and especially the lower, surface showed diffuse ecchymotic hematomas in the capsule. The cut surface disclosed a mottled yellow-pink appearance. About the blood vessels of the hepatic trinities, outside their walls, was a dark purple hematoma. The wall of the gallbladder contained a diffuse hematoma. The left adrenal weighed 12 Gm. A diffuse hematoma was present about the gland and in the periadrenal tissue. There was slight autolysis of the medulla but no hemorrhage. The right adrenal, which weighed 16 Gm., showed similar changes. The left kidney weighed 220 Gm., and the capsule stripped with ease. There were multiple petechial hemorrhages, and the cut surface disclosed acute passive congestion. The pelvic mucosa was severely congested, and a diffuse hematoma outside the mucosa extended 6.5 cm. down the ureter. Hematomas were also present within the ureteral mucosa. The gross appearances of the right kidney, which weighed 190 Gm., and the ureter were similar to those on the left, including the same distance of hemorrhage from the pelvic mucosa. There was congestion of the mucosa of the rectum, urethra and bladder, the latter showing a few petechial hemorrhages. There was cystic cervicitis. Fluid blood was present over the surface of the endometrium; a small myometrial leiomyoma was present. The ovaries were cystic; the uterine ligaments contained a diffuse hematoma.

Microscopic Pathologic Observations: The examination of the spinal cord revealed congestion with slight subarachnoid hemorrhages. The essential lesions found in the brain consisted of small hemorrhages by diapedesis, which were most numerous in the white matter of the cerebral hemispheres but were also present in the cerebral cortex, brain stem and white matter of the cerebellum. Associated with this there was distension of the subarachnoid spaces by fresh blood and recent bleeding at the site of the softening in the right parietotemporal region. There was also severe dilatation of the arterioles and capillaries and some perivascular rarefaction of tissue. In some perivascular regions there was old blood pigment engulfed by histocytes. The secondary effects of the hemorrhagic disturbance consisted of severe edema of the parenchyma, manifested by distension of the interstitial spaces, swelling of the oligodendroglia and shrinkage of cortical neurons. There was also a mild proliferation of microglia and astrocytes in the white matter.

There was hemorrhage in the epicardial fat. The aorta showed slight atherosclerotic changes with calcification of the media. Acute congestion and edema of the lungs were present, with severe hemorrhages by diapedesis. Atelectasis, emphysema and fibrous pleuritis were observed. The trachea showed hemorrhages into the adventitia; there were hemorrhages into the serosa of the esophagus and stomach.

The thymus contained persistent lymphoid tissue, and fatty atrophy was present. The spleen revealed acute passive congestion. There were hemorrhages into the mesentery of the small intestines, and wandering cells were increased. The colon was normal except for increased mucin. There was congestion of the pancreas with slight hemorrhage by diapedesis. Extensive hemorrhage was present at the hilus of the liver and over the capsule with central brown atrophy and slight lipidosis of the parenchyma (fat stain). The gallbladder showed extensive hemorrhage beneath the serosa, with a subacute inflammatory infiltration, including eosinophils, and thrombosed veins. Periadrenal hemorrhage was present with leukocytic infiltration and loss of lipids from the inner zone of the cortex (fat stain). The kidneys were congested, and hemorrhage was present in the distal convoluted tubules. There was vasculitis in the pelvic adipose tissue, with abundant eosinophils. Hemorrhage had occurred beneath the pelvic epithelium. Slight interstitial peripelvic nephritis was present; fat stains were negative. The ureters revealed hemorrhage throughout the walls with eosinophils in an inflammatory exudate and severe mucosal congestion. Voluntary muscle showed hemorrhages in adjacent adipose tissue. Bone marrow of the ribs, sternum and vertebral bodies, following decalcification, was hyperplastic, about 90 per cent cellular, with periosteal hemorrhages. The breasts and bladder were essentially normal.

Pathologic Diagnosis[12]: Hypinosis was observed, with cerebral, subarachnoid, cardiac, renal, hepatic, pulmonary, periosteal, retroperitoneal and cutaneous hemorrhages. Other observations were: acute passive congestion of all organs; cerebral and pulmonary edema; angiitis in the wall of the gallbladder, renal pelves and ureters, with eosinophilia; hypersensitivity reaction; slight atherosclerosis of the aorta and its branches; slight lipidosis of the liver; edentulism; fibrous pleuritis; an old appendectomy, and persistent thymus. There was positive reaction to a postmortem serologic test (4 plus, Kahn), indicating possible latent syphilis. A culture of blood from the heart yielded no growth.

---

[12] The gross and microscopic observations were made by the Department of Pathology and Neuropathology, University Hospital, Universit of Michigan, Ann Arbor.

COMMENT

Dicumarol® poisoning is characterized by hemorrhage. In cattle fed spoiled sweet clover hay, as pointed out first by Schofield[13] and later by Roderick,[14] bleeding occurred at sites of stress and was more commonly present in fascia of muscles and subcutaneous tissues, with the local blood vessels showing no pathologic changes. Schofield described gross lobular lesions in the liver to which he attributed the hemorrhagic tendency. Roderick attributed these observations to postmortem changes and found no serious impairment in hepatic function.

McCarter, Bingham, Meyer and Pohle[15] reported the pathologic observations after the administration of dicumarol.® In dogs dying of acute poisoning after massive doses of dicumarol® the outstanding morphologic evidences of toxicity were: (1) gross or microscopic hemorrhage, (2) toxic lesions of small vessels, (3) acute renal glomerular swelling and (4) toxic lymphoid tissue reactions. They particularly emphasized the presence of serious damage to the small blood vessels. No consistent lesions of the liver attributable to dicumarol® were discovered. In a series of dogs which had received dicumarol® at levels of therapeutic dosage, the only toxic tissue effect observed was in the hyperplastic reactive lymphoid tissue. In a series of 5 autopsies on human beings to whom dicumarol® in therapeutic doses had been administered, no typical lesions were observed which could be unequivocally charged to dicumarol.®

Ferraro and Roizin[16] reported histologic changes in various tissues and viscera of chicks due to dietary vitamin K deficiency with hypoprothrombinemia. A diffuse hemorrhagic diathesis was represented by small and large hemorrhagic involvement of subcutaneous tissues, muscles, joints, bone, periosteum, heart, thymus, lungs, intestines, liver, kidneys, spleen, gonads, meninges, spinal cord and brain. Notable changes in the walls of veins and arteries were emphasized, such as irregular dilatation, hypertrophy, hyperplasia and mild degeneration to complete rupture of the vessels.

Shlevin and Lederer,[11] reporting postmortem observations in a fatal case of uncontrollable hemorrhage in a human being following dicumarol® therapy, emphasized decided engorgement of all blood vessels, excepting the large trunks, which was most pronounced in the capillaries, arterioles and venules. Where the hemorrhages occurred in various tissues and organs, the vessel walls were consistently found to be intact with broad lumens. They suggested that these extravasations were due to diapedesis between cells rather than to rupture or solution of continuity of the cell walls. They reported that the liver showed many areas with distended sinuses filled with unclotted blood. This also was a prominent feature in dogs poisoned with excessively large doses of dicumarol.®[15]

Our patient demonstrated many of the aforementioned changes, in addition to gross hemorrhage into the brain, kidney and liver. The associated gross destruction of brain tissue was probably the immediate cause of death.

CONCLUSION

The most important of all contraindications to the use of dicumarol® is lack of reliable laboratory facilities for prothrombin determinations. Employment of this beneficial drug without laboratory control is hazardous and may result in fatal widespread hemorrhage.

Caution should be observed in the administration of dicumarol® to patients with severe hypertension, particularly if there is a past history of cerebrovascular accidents.

EVALUATION OF AEROSOL-NEGATIVE PRESSURE THERAPY

Given Once Daily in Chronic Purulent Sinusitis

EDUARDO R. PONS Jr., M.D.
WALTER M. GLASS, M.D.
and
BETTINA GARTHWAITE, M.D.
New York

The purpose of this investigation is a critical evaluation of aerosol alternating negative pressure therapy given once daily in cases of chronic purulent sinusitis.

The inhalation route for administration of various medicaments, such as bronchodilator and bronchovasoconstrictor drugs, and in more recent years chemotherapeutic and antibiotic groups of drugs, is now well established in the treatment of certain types of bronchopulmonary disease.[1] Inhalational therapy of diseases of the upper part of the respiratory tract has also been extended to include antibiotic aerosols. Some favorable clinical results were reported by Vermilye[1j] in cases of acute sinusitis and acute pharyngitis and in acute exacerbations of chronic sinusitis. However, it was first demonstrated by Barach and his co-workers[2] that alternating application of negative pressure with inhalation of penicillin aerosol was necessary to insure

the introduction of penicillin into the maxillary sinuses and thereby prove efficacious in therapy of chronic sinusitis.

In cases of chronic purulent sinusitis such treatment performs four functions: shrinkage of congested mucous membrane, drainage of exudate from the paranasal sinuses during the phase of suction, ventilation of the sinuses with oxygen or air and introduction of antibiotic aerosol to the diseased site.

Barach and his co-workers previously reported the clinical usefulness of nasal penicillin aerosol combined with alternating negative pressure in therapy of acute and chronic sinusitis.[3] The original apparatus has been modified into a simplified unit.[4] Experimental evidence has been presented suggesting that ventilation, drainage and deposition of penicillin aerosol occur in the paranasal sinuses when this apparatus is used. An oxygen flow of 5 to 8 liters per minute produces, by means of a glass venturi tube, a negative pressure of approximately 60 to 70 mm. of mercury in the maxillary antrums and slightly higher pressures in the nasal passages. Higher oxygen flows result in progressively higher negative pressures within the nose but very slight increase in negative pressure within the antrums, necessitating the conclusion that above a certain negative pressure the increased suction is not transmitted to the antrums because of closure of the ostiums and therefore defeats the purpose of the suction phase of treatment. In subjects with oroantral fistulas, demonstration of penicillin in the antrum was possible after inhalation of the drug in aerosol form when the sinus negative pressure apparatus was used. It was shown that some of the penicillin aerosol condensed inside the nasal passageway and was sucked into the antrum in liquid form. Finally, it was demonstrated that penicillin introduced into the antrum in aerosol form is actually deposited therein and can be recovered in later irrigation for at least two hours after completion of the aerosol treatment.[3]

McAuliffe and Mueller[5] have described a modification of this apparatus, which can be used in otolaryngologic practice with any standard vacuum and pressure pump to introduce penicillin aerosol into the paranasal sinuses by using calibrated suction and pressure. These authors reported that the method gave good results in infections of the upper part of the respiratory tract, including infections of the paranasal sinuses.

In evaluating the effect of any therapy of sinusitis it must be realized that acute purulent sinusitis is usually a self-limited disease and sooner or later resolves completely in the majority of instances, no matter which of the usual forms of treatment are employed. Some cases of chronic disease are also subject to partial remissions and exacerbations of symptoms. Even in chronic purulent sinusitis no 2 cases are alike. Evaluation of this group as a whole is complicated by the differences in the individual cases because of factors such as the severity of symptoms, duration of the disease and appearance of the physical signs. One patient may complain of only moderate postnasal discharge and nasal congestion over a period of a year or two, present minimal signs of sinusitis and return a few mucopurulent clumps on antral irrigation; while another patient may complain of profuse anterior and posterior nasal discharge, nasal blockage, headache, cough and expectoration over a period of many years, give a history of repeated sinus irrigations and surgical procedures and present 4 plus foul broken-down pus on antral irrigations. Allergic factors also contribute to the variability of the disease—some cases are primarily allergic in nature with a secondary bacterial infection, while other cases are primarily bacterial in nature with a superimposed bacterial allergy. There are other cases in which it is impossible to determine whether the allergy or the infection is the primary cause of the disease. Recently, emphasis has been placed on the importance of psychosomatic influences on the behavior of diseases involving the nasal mucous membranes.[6]

Since the principles of shrinkage and suction in themselves are well established otolaryngologic methods of treatment, we have also attempted in the present study to analyze more accurately the role of the antibiotic versus the role of shrinkage and drainage. The major portion of this report deals with the results of therapy in two comparable series of cases of sinusitis treated with this method in identical fashion except for the omission of penicillin in the group that served as a control. In addition, the experience with streptomycin aerosol in gram-negative sinus infections is presented. Clinical impressions on the practical applications of the method in general and rhinologic practice are discussed, and indications for its use are postulated.

METHODS

Selections were made from patients of the Nose and Throat Department of Vanderbilt Clinic. In selecting cases of chronic purulent sinusitis for inclusion in the series all the following criteria had to be satisfied: (1) a history of continuous symptoms of sinusitis for at least six months prior to treatment, (2) evidence of infection of the nasal mucosa with the presence of pus in the nose either before or after shrinkage, (3) cloudiness of one or more sinuses on transillumination, (4) roentgen evidence of sinusitis, (5) purulent returns on antral aspiration and (6) the appearance of pathogens on culture. A history of the disease was obtained in all patients, with special emphasis on allergic factors, past or associated diseases of the respiratory tract and previous otolaryngologic therapy. A careful examination of the nose, nasopharynx and oropharynx with transillumination of the sinuses was done in each case in order to study the condition of the nasal mucous membrane, to detect signs of allergy, to document the existence of purulent infection and to exclude factors that might interfere with drainage from the paranasal sinuses (polyps, deviated septum, hypertrophied turbinates, etc.). If the sinus ostiums were mechanically blocked, surgical correction was performed prior to acceptance of the patient for therapy.

Routine sinus roentgen examinations were made in all cases. Following this, cocainization of the inferior meatus, antral puncture with a trocar and aspiration of the antral contents were done. The latter was made with a sterile syringe and served both to obtain material for bacteriologic study directly from the antrums and further to establish objectively the presence of purulent infection. This was followed in most cases by a diagnostic antral irrigation, in order to note the amount and nature of the antral contents. In a few patients, i. e., children and hypersensitive persons, nasal cultures of the purulent overflow from the sinuses were taken after prior shrinkage and cleansing of the nasal passages.

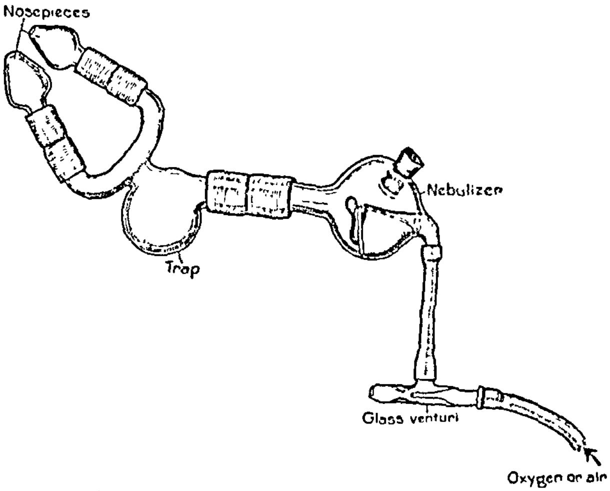
The apparatus used for treatments was the simplified one developed by Barach and his co-workers,[4] consisting of a glass nebulizer, trap and olive-tipped nose pieces which are connected to a source of oxygen or compressed air by means of rubber tubing into which a glass venturi tube is inserted (figure).[7] In using the apparatus, the patient holds the nose pieces tightly in the nostrils. By holding the thumb over the open end of the venturi, oxygen or air is forced into the nebulizer, producing the aerosol which flows into and fills the nasal cavities. The patient gently breathes through his mouth three times, after which he removes his thumb from the open end of the venturi, closes his mouth and swallows. The oxygen or air now passes out of the open end of the venturi, creating a negative pressure in the apparatus, which is transmitted to the paranasal sinuses when the palate is closed in the act of swallowing. The venturi is then closed again with the thumb and the procedure repeated until aerosolization of solution in the nebulizer is completed. When used in alternation with nebulization, suction from the venturi allows alternating partial emptying and filling of the paranasal sinuses with oxygen or air heavily laden with nebulized particles.



Drawing of the apparatus used in this study.

All treatments were given once daily, six days a week, and were continued up to four weeks. All patients were individually instructed in the correct use of the apparatus. The great majority of patients were treated in the clinic for the entire length of treatment and were under close supervision at all times. Only a few patients were allowed to take treatment at home, after preliminary training consisting of at least one week of daily clinic treatments.

After initial antral culture, with bacterial sensitivity tests in some instances, the appropriate antibiotic was selected. Penicillin treatments consisted of 250,000 units crystalline penicillin[8] in 2 cc. of 1 per cent ephedrine sulfate in saline solution, with rinses of 1.0 and 0.5 cc. distilled water each. Streptomycin[9] dosage was 0.5 Gm. of the calcium chloride complex, in 2 cc. of 1 per cent ephedrine sulfate in saline solution with 1.0 and 0.5 cc. distilled water rinses. Ephedrine treatments were identical except for the omission of antibiotics. Inactivated penicillin was used in addition to the ephedrine preparation in 5 control cases in which there was a decided psychosomatic component. Nebulization of solutions was effected with oxygen at 6 liters per minute flow except for a few of the patients treated at home who used a foot pump instead of oxygen as a source of power for nebulization. The time for a single treatment averaged thirty minutes. By keeping the volume of solutions identical and by using the same flow and uniform technic, we maintained the degree and length of time of application of negative pressure approximately equal in all cases.

In each patient, symptoms of headache, coryza, nasal obstruction, amount and nature of anterior and posterior nasal discharge, cough and expectoration were followed daily, as well as signs of possible toxic reactions. Examinations of the nose and throat with transillumination of the sinuses were conducted weekly, and in some cases interval sinus roentgenologic examinations were done. At the end of treatment roentgenograms were again made and compared with previous ones. A final nose and throat examination, antral puncture, aspiration of antral contents for culture and a final diagnostic irrigation were done, the latter to note any change in the amount and nature of the antral contents. An attempt was made to follow all patients' symptoms and signs of sinusitis during the first month after treatment and at later intervals.

It must be remembered that the program followed in this series of clinic patients is probably not the ideal one for obtaining optimal results. It is believed that treatments given several times daily would be superior in terms of continued relief of nasal obstruction and maintenance of a therapeutic local concentration of antibiotic drug within the sinuses. The one treatment a day method was used in this study because it was the most practical method that afforded strict daily control and supervision of individual clinic patients. It was also felt that administration of one massive treatment daily, six days a week for one month would be comparable to the use of four smaller daily treatments of over a two week period.[3]

Except for the separation of cases in which there were allergic manifestations, further breakdown of the series to consider factors such as duration of symptoms, severity of the disease and nature of antral contents was found to be impractical, as it resulted in groups containing very small numbers of cases.

In each case, separate evaluation was made of symptoms, physical signs, roentgenograms, antral contents and bacteriologic aspects. Improvement in the symptoms, physical and roentgen appearance was classified as being slight or none, moderate or decided, and the usual margin of human error prevailed in deciding in which category the individual cases belonged. In general those patients that at the end of treatment presented a normal appearing nose, had no symptoms and a normal roentgenogram were tabulated as showing decided improvement in each category. Those patients that did not have complete normality in each respect were classified as showing moderate, slight or no improvement, as seemed appropriate.

The quantity and gross nature of antral contents provided another measure of therapeutic effectiveness which was termed as decided when the final irrigation was entirely clear, moderate when an initial observation of broken down pus gave way to clumps or shreds, and slight to none when no change occurred or in cases of bilateral disease when there was only partial one-sided change. Bacteriologic changes could be determined by comparison of organisms cultured from the antrum before and at the end of treatment. In summarizing these changes, cases were grouped according to disappearance of all organisms, complete or partial disappearance of gram-positive or gram-negative organisms and, finally, as no change in bacteriologic observations.

RESULTS

The penicillin and ephedrine control groups number 23 patients each. In all instances, some degree of involvement of the maxillary sinuses was present. In about half the cases these were the only sinuses found to be diseased; when multiple sinus infection occurred the ethmoids were involved more often than the frontals or sphenoids. The condition in about two thirds of the cases was bilateral. The average duration of the disease was eleven years; approximately half of the patients previously had had antral irrigations and/or nasal surgical treatment with temporary or no effect on the disease. The similar incidence of all these factors in both the penicillin-treated and ephedrine-treated patients justified the assumption previously made on the basis of history, physical signs and roentgen observations, that the two groups were comparable. This was further supported by an almost equal distribution of bacterial flora in the material studied from both groups of cases.

In many patients who presented themselves with symptoms suggestive of chronic sinusitis, complete otolaryngologic examination revealed only the presence of a purely allergic or vasomotor rhinitis, or of deviated septums, polyps or hypertrophied turbinates. In many instances of true chronic purulent sinusitis the observation of mechanical blocking of the sinus ostiums revealed factors amenable to surgical correction without which the introduction of antibiotic aerosol into the sinuses was impossible. In some patients dental foci had to be eradicated in order to control successfully the infection. Other cases were rejected because symptoms of chronic sinusitis were found to have solely a psychosomatic basis. Many of the patients with organic sinus disease had superimposed functional complaints which further complicated evaluation of results.

1. Comparison of Penicillin and Ephedrine Control Groups (table 1).—Symptoms: About equal numbers of patients in both ephedrine-treated and penicillin-treated groups showed decided, moderate and slight-to-absent symptomatic improvement (table 1, A). Qualitatively, the response to treatment was also similar. Some of the patients with severe long-standing complaints showed a dramatic change in symptoms. Striking relief of chronic headache was at times seen, concomitant with drainage of purulent secretions into the trap of the apparatus. Nasal obstruction was relieved temporarily for one to six hours or longer following treatment. In many of the patients showing a favorable response, anterior and posterior nasal discharge increased during the first three or four days of treatment and decreased gradually thereafter. The diminution of postnasal drip was accompanied by reduced cough and expectoration. In patients with associated bronchopulmonary infection, a significant decrease in cough and expectoration, with loss of most of the purulent element in the sputum, occurred only in the group treated with penicillin aerosol.

Physical Observations: Seven of the penicillin-treated patients showed decided and 8 showed moderate improvement. Two of the ephedrine-treated patients showed decided and 3 showed moderate improvement (table 1, B).

Roentgenograms: Eleven of the penicillin-treated patients showed decided or moderate improvement, while only 4 of the ephedrine control patients showed comparable changes (table 1, C).

Antral Contents: There were no over-all differences in 19 penicillin-treated and 20 ephedrine-treated patients. Half of the patients in each group showed no change in the character and amount of antral contents (table 1, D). However, of the patients showing fluid and broken down pus at the start of treatment, the condition in 5 out of 13 treated with penicillin cleared entirely, while 2 out of 11 patients treated with ephedrine showed disappearance of the antral pus.

Bacteriologic Observations: Mixed infections were found in about 60 per cent of all the cases. The commonest organisms found in the antrums in order of incidence were: Hemophilus influenzae, hemolytic Staphylococcus aureus, pneumococci and microaerophilic streptococci. The bacteriologic changes before and after treatment are summarized in table 4. Some changes in bacterial flora could be seen to occur in the control cases in which the ephedrine preparations were used, but changes tended to be more pronounced in the patients that were treated with penicillin. Only a small number of patients showed complete disappearance of all organisms at the end of treatment, 2 in the penicillin group and 3 in the ephedrine control group. Six of the penicillin group showed disappearance of all gram-positive organisms with persistence of the original, or appearance of new, gram-negative flora at the end of treatment. This also is seen in sputum cultures of patients with bronchopulmonary infection treated with penicillin aerosol.[1b] None of the ephedrine control cases showed this change. There was no bacteriologic change in 10 ephedrine control patients and in 5 patients treated with penicillin.

TABLE 4.—*Bacteriologic Changes in Chronic Sinusitis*

Treatment	*Penicillin*	*Ephedrine Sulfate*	*Penicillin*	*Ephedrine Sulfate*
Disappearance of organism	2	3	..	..
Complete disappearance of gram-positive, with persistence or appearance of gram-negative flora at end of therapy	6	..	1	2
Partial disappearance of gram-positive from mixed flora at end of therapy	5	4	..	1
Appearance of gram-positive organisms	..	2	..	..
No change	5	10	3	4
No observations made	5	4	1	..
Total	23	23	5	7

Direct demonstration of the entrance of penicillin into the antrums in cases of known purulent sinusitis was possible by determination of penicillin levels in pus aspirated from the antrum immediately after a penicillin treatment. In 6 cases in which observations were made concentrations of penicillin ranging from 0 to 8.0 units per cubic centimeter of antral pus were found. Of these patients, 3, who showed 1.4, 7.0 and 8.0 units per cubic centimeter, also had improvement in antral contents and bacteriologic observations. Two patients, with 0 and 0.8 unit per cubic centimeter, showed no improvement in these respects, while in one test resulting in a penicillin level of 0.7 unit per cubic centimeter the antral flora became gram-negative.

The patients showing anaerobic bacterial flora (7 with microaerophylic streptococci, 2 with unclassified anaerobes, 1 with anaerobic gram-negative rods) showed in general a poor response to aerosol treatment given once daily. All 6 such patients that had ephedrine control treatment showed no improvement; of these, 4 were subsequently given penicillin aerosol and 2 improved. Three other patients were treated with penicillin and 1 with streptomycin, without significant improvement. One patient with an anaerobic infection, who showed no change on a full course of penicillin aerosol followed by six antral irrigations, was cured by a right maxillary antrostomy, and has remained completely asymptomatic and clinically free of disease after an eight months' follow-up. In another similar case the patient, who had received a full course of penicillin aerosol with no improvement, was cured clinically by seventeen antral irrigations over a period of five weeks and has likewise remained free of disease after a one month follow-up.

Patients That Received Both Penicillin and Ephedrine Treatment: A group of 10 patients, who are included in the series already presented, afforded an opportunity to serve as their own controls, since all 10 patients were treated with ephedrine aerosol with no improvement and were then given penicillin aerosol. With the latter treatment, there were also therapeutic failures with penicillin in 5 of the 10 cases. Four patients showed moderate over-all improvement with penicillin as compared with ephedrine and 1 patient showed decided improvement with penicllin.

II. Allergic Patients.—The number of patients with predominantly allergice factors was too small to permit comparison between the penicillin-treated and ephedrine-treated patients (table 2). Nine out of 12 patients showed pansinusitis, and 8 had a history of previous polypectomies. As a rule, symptomatic relief was obtained as in the nonallergic patients and was enhanced by the use of oral antihistaminics. In some instances improvement on physical examination could be found, but there were equally few or no changes in roentgenograms, antral contents or bacteriologic observations in both series (table 4).

III. Streptomycin Therapy.—A group of 10 patients with complete or predominant gram-negative flora was treated with streptomycin aerosol. The results, classified according to the presence or absence of allergic factors, are shown in table 4. It can be seen that frequency of symptomatic relief tended to be similar to that obtained with ephedrine or penicillin in comparable types of cases. Objective evidence of improvement in physical examination, roentgenograms, antral contents or bacteriologic studies was slight. Of 7 patients studied bacteriologically before and after treatment, 4 showed disappearance of the original gram-negative organisms at the end of treatment, but at this time 5 patients showed the presence of some gram-negative bacteria in the antrums. In 1 case, Escherichia coli, which at the start of treatment was sensitive to 0.6 microgram of streptomycin per cubic centimeter, showed resistance to 10 micrograms per cubic centimeter at the end of fifteen treatments. In another case E. coli was obtained at the end of treatment which was resistant to 100 micrograms of streptomycin per cubic centimeter.

IV. Follow-Up.—In 20 of the penicillin-treated patients, follow-up observations were made within the first month after treatment. Ten of these patients maintained the moderate or decided improvement they had made during therapy. Seven patients (a third of the total) showed recurrence of symptoms during this time; of these 2 had good over-all results, 3 had moderate improvement and 2 poor results at the end of their courses of treatment. Three patients, all with poor results, were referred for other forms of treatment. Because of the relatively short time the study was in progress, late follow-ups (four to eight months posttreatment, including the winter season) could be obtained in only 6 penicillin-treated patients. The disease in all of these was severe, averaging ten years in duration. Although 4 of these patients had flare-ups in symptoms sometime during this period, they all responded to further courses of penicillin aerosol therapy.

Of the 18 ephedrine-treated patients seen during the first month after treatment, 2 maintained improvement, 6 had recurrences and 10 showed poor results and were given penicillin aerosol.

Similar frequency of recurrences was noted in the small number of patients comprising the allergic groups and streptomycin-treated patients.

V. Reactions.—Of the 23 nonallergic and 5 allergic patients who received penicillin aerosol, 3 showed reactions that were severe enough to warrant cessation of treatment. One patient had a fever, pruritus and generalized erythema after nine treatments, and another had headache, chills and urticaria after thirteen treatments. Both these reactions subsided three days after discontinuation of penicillin aerosol and administration of tripelennamine hydrochloride (pyribenzamine hydrochloride®), 50 mg. four times daily. A patient with previous acute glomerulonephritis, who was receiving his second course of penicillin aerosol treatment for hemolytic streptococcus sinusitis, experienced severe myositis and fever. This case, which was studied at the Presbyterian Hospital and is believed to represent an unusual reaction to penicillin, will be the subject of a future report.[10] An additional patient who previously had had repeated oral penicillin aerosol inhalations for bronchiectasis, during which a sore red tongue had developed, had to discontinue treatments after five days because of the onset of this condition.[1h]

There were no complaints of local irritation of the nose or throat due to penicillin aerosol. Several patients had a brownish coating of the dorsum of the tongue while receiving penicillin aerosol. This was asymptomatic but persisted for several weeks after cessation of treatment.

Most of the patients receiving streptomycin complained of severe nasal irritation and coryza, but no systemic toxicity was noted. One patient with associated bronchial asthma had an exacerbation of this condition throughout her course of streptomycin therapy (eighteen days). The asthma subsided three days after treatment was discontinued. No local or systemic symptoms from ephedrine administration were seen.

COMMENT

It is recognized that corrective surgical procedures of obstructions to drainage from the sinuses, necessary to the proper application of aerosol therapy in some of our cases, in themselves caused some of the improvement noted in both penicillin-treated and ephedrine-treated patients. In like manner, a certain amount of therapeutic credit is due to the power of suggestion of the aerosol apparatus over some patients with psychosomatic components of the disease. Inactivated penicillin was used in those ephedrine control cases with an obvious functional element in an attempt to minimize the suggestive effect of the antibiotic.

Symptomatic improvement of sinusitis during treatment in the cases studied apparently does not depend on the administration of penicillin, but is the result of the improved ventilation and drainage of the sinuses which both methods of treatment provided. The decrease of cough and expectoration seen in cases of sinusitis with associated bronchopulmonary infection can be attributed to the topical application of penicillin aerosol in the lungs during treatment. With equal conditions of sinus drainage, the decided improvement of the physical appearance of the nose and transillumination of the sinuses in the penicillin series suggests that penicillin is the responsible agent. The small number of cases in both categories in which there was complete or partial roentgenographic resolution was not entirely unexpected in this group of patients with chronic disease, a number of whom had had repeated sinus operations and many of whom had had sinus disease for ten or more years. However, the figures show a tendency toward more favorable results in the patients that received penicilin aerosol. Better results were also obtained in the penicillin-treated patients showing fluid broken down pus in the antrums, indicative of a severe degree of infection; however, no significant differences in change of antral contents were noted between the two series when considered as a whole. The bacteriologic changes observed in the penicillin-treated group are thought to be the result of the local bacteriostatic or bactericidal action of penicillin within the paranasal sinuses.

Burtoff,[11] using one or two weekly antral irrigations with daily instillation of penicillin in solution into the antrums in cases of chronic maxillary sinusitis, observed no clinical difference in the results of treatment with saline solutions or penicillin. The use of penicillin, however, resulted in sterile antral cultures after the third or fourth irrigation.

The therapeutic action of ephedrine aerosol and negative pressure is evident in the control cases in which there was improvement. Although it is appreciated that this is a small group, the addition of penicillin to the treatment, in cases of infection with penicillin-sensitive organisms, appears to result in an enhancement of the therapeutic effect. Further suggestive evidence that penicillin aerosol is superior to ephedrine aerosol alone is provided by the results in the 10 patients who served as their own controls.

The response of cases of allergic sinusitis to either ephedrine or ephedrine-penicillin treatment is not pronounced. The swollen state of the allergic nasal and sinus mucous membrane, together with its tendency to develop polypoid degeneration, constitutes a barrier to the ventilation and drainage of the sinuses and to the entrance of penicillin aerosol.

Streptomycin aerosol treatment of chronic sinusitis due to infection with gram-negative bacteria has its limitations in that such organisms are prone to become resistant to the antibiotic in a relatively short time. With such time limitations, intensive treatment several times daily seems indicated; however, the local irritative properties of streptomycin may limit the frequency of administration. Doses of 0.2 or 0.3 Gm. three or four times a day may be better tolerated than those used in this study. That in isolated cases this treatment is successful is shown in 2 of our patients with mixed gram-positive and gram-negative infection, who after treatment with penicillin aerosol still showed lack of improvement and the presence of gram-negative organisms in the antrums, which were subsequently eradicated by streptomycin therapy.

---

[10] Fisk, S. C., and Curran, G. L.: To be published.

[11] Burtoff, S.: Evaluation of Diagnostic Methods Used in Cases of Maxillary Sinusitis, with a Comparative Study of Recent Therapeutic Agents Employed Locally, Arch. Otolaryng. **45**: 516-542 (May) 1947.

In order to obtain optimal results with antibiotic aerosol therapy, it is recommended that antral cultures and antibiotic sensitivity tests of organisms be made prior to institution of treatment and that the appropriate antibiotic be selected as was done in this series. When direct antral cultures are not feasible, nasal cultures of the purulent overflow from the sinuses should be taken.

Although the results obtained with penicillin aerosol tended to be better than with ephedrine aerosol, the over-all effect of penicillin aerosol therapy, as used in these clinic patients with chronic sinusitis, does not justify enthusiasm for the single treatment per day method. Only 3 out of the entire penicillin-treated group showed decided improvement in all five categories studied, and 2 of these 3 patients had a recurrence of symptoms and signs two months after cessation of therapy. In considering the penicillin-treated group as a whole, it is noted that a high percentage of recurrences was evident even after a brief follow-up period. It should be noted also that 7 of the 23 patients treated with penicillin aerosol showed little or no improvement in their disease.

In the present series the most gratifying subjective and objective results were obtained in those patients with severe long-standing chronic purulent sinusitis presenting a history of multiple nose and sinus operations and irrigations with little or no relief of symptoms. These patients, almost without exception, did exceedingly well while receiving penicillin aerosol, but recurrence of symptoms after cessation of treatment was the general rule. These flare-ups responded satisfactorily to subsequent courses of penicillin aerosol with negative pressure. Many of these patients reported that this therapy gave them more relief than they had been afforded by any other form of treatment. A number of children were treated successfully, and it was felt that the method was of definite value in the treatment of sinusitis in children, as the use of the apparatus was learned rapidly, and the treatments were taken without resistance or fear of pain on the part of the patient. The same considerations held true in the cases of the adults who were unable to tolerate sinus irrigations. Another group of patients that did well was the one with concomitant chronic sinus infection and chronic pulmonary disease, for the penicillin aerosol had a simultaneous beneficial effect on both processes.

In comparison of the relative merits of antibiotic aerosol therapy in the ordinary case of chronic purulent sinusitis with other forms of treatment of this disease (nasal shrinkage and suction, sinus irrigations, Proetz displacement therapy and the building up of general body nutrition and resistance) it was the clinical impression of the investigator (W. M. G.) with previous experience in these methods that penicillin aerosol-negative pressure treatment alone, given once daily, was not superior to the accepted forms of treatment. Better results may be expected with three or four daily treatments. It was felt further that biweekly or triweekly irrigations of the infected sinus or sinuses gave a more rapid response than did a single daily treatment with penicillin aerosol. Although in this study no series of patients was treated with other methods, good results were obtained with antral irrigation and surgical treatment in isolated cases of severe anaerobic maxillary sinusitis in which there had been no improvement from penicillin aerosol therapy.

In the ordinary case of chronic purulent sinusitis, it is thought that optimal results with this method may be obtained when it is used several times a day in conjunction with periodic irrigations of the appropriate sinuses. In this way the purulent sinus contents would be evacuated, thus making possible direct application of the antibiotic aerosol to the diseased mucosa. Repeated sinus irrigations at intervals of about a week would serve to keep the mucosa exposed to the action of the aerosol. By using this method in conjunction with penicillin aerosol treatments taken at home three or four times daily, one might reduce the frequency of sinus irrigations and achieve quicker control of the infection. Dosage of 100,000 units of crystalline penicillin in 1 cc. of 1 per cent ephedrine sulfate in saline solution or 0.25 per cent phenylephrine hydrochloride (neo-synephrine hydrochloride®), followed by two 0.5 cc. distilled water rinses, is suggested. A study of this method of treatment is contemplated at present.

It is emphasized that competent otolaryngologic appraisal and pretreatment surgical correction of any mechanical blockage of sinus ostiums are absolute prerequisites to the intelligent application of aerosol-negative pressure therapy.

SUMMARY AND CONCLUSIONS

The results in 68 cases of chronic purulent sinusitis with aerosol-negative pressure therapy once daily with and without antibiotics are presented. Comparison of results in 46 nonallergic patients—23 treated with penicillin-ephedrine aerosol and negative pressure and 23 treated similarly without penicillin—provides suggestive evidence that the antibiotic enhances the therapeutic effect. In 12 patients with chronic sinusitis with predominantly allergic factors there was no significant improvement from treatment by the methods described. Ten patients with chronic sinusitis infection due to gram-negative organisms treated with streptomycin aerosol showed in general a poor therapeutic response.

Clinical impressions as to the relative value of penicillin aerosol with negative pressure given once per day as compared with the usual methods of treatment of chronic purulent sinusitis are presented and indications for this type of therapy are suggested. In the ordinary case of chronic purulent sinusitis, antibiotic aerosol therapy given once daily appears to have no superiority over accepted methods of treatment of sinusitis. This method is suggested, however, as a treatment of choice in cases of long-standing chronic disease in patients who have had repeated sinus irrigations and/or extensive sinus surgical treatment with poor response, children and adults who do not tolerate sinus irrigations and in patients with associated chronic bronchopulmonary disease. It is felt that optimal results with this method of therapy would be obtained by combination of multiple daily aerosol-negative pressure treatments with weekly sinus irrigations.

EXPERIENCES WITH NITROGEN MUSTARD THERAPY

C. C. SHULLENBERGER, M.D.
CHARLES H. WATKINS, M.D.
and
ROBERT R. KIERLAND, M.D.
Rochester, Minn.

Until recently, the palliative treatment of lymphoblastoma and other neoplastic diseases has depended almost entirely on the use of irradiation by roentgen rays or radium. With the recent introduction of the nitrogen mustards as potential therapeutic agents in this field, a concentrated effort has been made by various groups of investigators [1] to determine whether there are any specific indications for the use of these substances in place of, or as an adjunct to, irradiation therapy. Since it appears that the biologic effects of the nitrogen mustards and the qualitative clinical response caused by them are similar to, if not identical with, those exerted by irradiation,[2] and since their availability and ease of administration confer definite advantages over irradiation therapy, it becomes a matter of some importance to know what may be expected of these agents when they are employed under certain clinical conditions.

Two fundamental questions are raised. First, is there any advantage to the patient in the use of nitrogen mustard instead of irradiation? An answer to this question can be provided only by comparing, over a protracted period, the results obtained by the administration of nitrogen mustard alone with those obtained by the use of irradiation alone in a similar group of cases. Second, in cases in which the patients have failed to respond or have become refractory to irradiation, is there reasonable hope that nitrogen mustard can still effect clinical remissions? It is the primary purpose of this report to attempt to answer this latter question by an analysis of the results of nitrogen mustard therapy in certain cases in which the patients have been observed at the Mayo Clinic in the sixteen months prior to writing. We are not in a position to provide an answer to the first question, since our experience with regard to the lymphoblastomas has largely been limited to cases in which the disease had been present for a long time and had been treated extensively by irradiation and in which a greater or lesser degree of resistance to irradiation had developed. Secondary objectives of this report will be to present data on nitrogen mustard therapy in diseases other than lymphoblastoma and to call attention to some untoward reactions to this agent.

For a consideration of the fundamental nature of the nitrogen mustards and their mode of action, the reader is referred to the report of Gilman and Philips.[2b] The immediate toxic effects of these agents and their effect on the hemopoietic and other tissues have been described by Gilman and Philips [2b] and by Jacobson and others.[1b] The immediate toxic effects of the administration of these agents, notably nausea and vomiting, do not seem to be a matter of much concern, since they are transient and often tend to decrease in severity during the course of treatment. However, the profound effects of nitrogen mustard on the hemopoietic tissues may result in anemia, leukopenia or thrombocytopenia of severe degree. This makes it mandatory that the physician employing these agents warn the patient of this hazard, that he follow the blood cell counts carefully for at least four to five weeks after therapy has been discontinued and that he be prepared to treat severe leukopenia or thrombopenia should such serious complications arise.

METHOD OF TREATMENT

The nitrogen mustard employed in all of the cases which form the basis of this report was methyl-bis (β-chloroethyl) amine hydrochloride. With few exceptions, a course of treatment consisted of intravenous injections, on four consecutive days, of 0.1 mg. of this material per kilogram of body weight. The total dose for any course, therefore, was 0.4 mg. per kilogram of body weight. In a few cases, it was necessary, because of excessive nausea and vomiting, to lengthen the interval between injections or to terminate the treatment after two or three injections, instead of the usual four, had been administered. It has been our experience that 150 to 200 mg. of pyridoxine hydrochloride, given intravenously at the time of the injection of the nitrogen mustard, often will reduce the severity of the nausea and vomiting which so frequently follow the administration of the latter. As a general rule, we have permitted six weeks to elapse between any two courses of nitrogen mustard, although, in a few instances in which more intensive treatment was indicated and the blood cell counts were satisfactory, we have given a second course between four and six weeks after the first.

In some of our cases of Hodgkin's disease and lymphosarcoma, because of a lack of response to nitrogen mustard, it seemed expedient to return to the use of roentgen therapy alone or to combine the two forms of treatment. In no case, however, did we return to roentgen therapy or to the combined treatment after the administration of nitrogen mustard was begun, unless it became apparent that the use of nitrogen mustard alone had failed to produce and maintain improvement. By proceeding on this basis, it seemed unlikely that any confusion would arise as to which agent was responsible for any effects noted.

RESULTS OF TREATMENT

In attempting to evaluate the effect of therapy on lymphoblastomas and other neoplastic diseases, it seems justifiable that one base judgment only on whether or not the agent employed significantly altered the fundamental lesions and prolonged the life of the patient, in relative comfort, to an extent significantly beyond what one might expect had the agent not been used. In some cases of Hodgkin's disease and lymphosarcoma, the disease runs a surprisingly indolent and protracted course, while in other cases, in which the histologic changes are essentially the same, the disease progresses much more rapidly. This variation makes the evaluation of therapy difficult. One, therefore, should be reasonably conservative in evaluating the results of treatment of this disease.

The subjective improvement which victims of these diseases note as a result of nitrogen mustard therapy, even after the lesions have become refractory to irradiation, is often pronounced. Diminution or disappearance of fever, increase in appetite and strength and decrease or absence of pruritus, for varying periods, are the rule, particularly after the first one or two courses. Yet, in our experience, these primarily subjective signs of improvement may be out of proportion to the strictly objective evidences of improvement, such as decrease in size of the lymph nodes or spleen, shrinking of pulmonary lesions, resorption of pleural fluid or regression of skeletal lesions. The true therapeutic efficacy of any agent is reflected in its ability to, at best, cause regression or resolution of existing lesions, or, at least, to prevent progression of the disease during the period of its utilization. For these reasons, we do not stress, in this report, the transient subjective indications of improvement; rather, we have sought to evaluate the results of therapy on the basis of objective changes in the lesions, the presence or absence of evidences of progression of the disease during treatment and the mortality rate during the period of observation.

TABLE 1.—*Results of Therapy in 18 Cases of Advanced Hodgkin's Disease*

				Behavior of Lesions During Period of Observation

* Before administration of nitrogen mustard.

† After the administration of nitrogen mustard was begun.

‡ NM denotes nitrogen mustard; RT denotes roentgen therapy.

§ Some of the lesions regressed, while others were unaffected or progressed. *In case 16 there was a complete remission of lesions of the superficial* lymph nodes for nine months, but the pulmonary lesion continued to progress.

Hodgkin's Disease.—The results of nitrogen mustard therapy, alone or in combination with irradiation therapy, in 18 cases of advanced Hodgkin's disease are summarized in table 1. In each of these cases, microscopic examination of a specimen of a lesion disclosed "lymphosarcoma, Hodgkin's type." All of the 18 patients previously had been treated repeatedly with roentgen rays, and the majority of the patients had noticed that their favorable response to this type of therapy had become less pronounced with each succeeding series of treatments.

In 14 of these cases either the patients died of progression of the disease or their physical condition deteriorated clinically during the period of observation after the institution of nitrogen mustard therapy. In cases 1 and 16, the death of the patients was not directly attributable to Hodgkin's disease but the disease obviously had progressed by the time death occurred. In this group of 14 cases, the duration of the disease prior to institution of nitrogen mustard therapy ranged from 13 to 72 months and averaged 31.8 months. In 5 of these cases, new lesions developed during the period of observation. The time that elapsed between the institution of nitrogen mustard therapy and the development of the new lesions ranged from 2 to 12 months and averaged 9 months. In 12 of the 14 cases, some or all of the original lesions showed clinical evidence of progression within 1 to 5.5 months after institution of nitrogen mustard therapy, the average being 2 months. In the 8 cases in which the patients died of progression of the disease, the duration of life after the institution of nitrogen mustard therapy ranged from 3 to 9.5 months and averaged 4.3 months.

In 4 cases, the clinical condition of the patients at the end of the period of observation apparently was the same as it had been when the administration of nitrogen mustard was started. In this group, the duration of the disease prior to the institution of nitrogen mustard therapy ranged from 27 to 132 months and averaged 80 months.

In the 18 cases of Hodgkin's disease, the lesions which showed measurable regression in response to nitrogen mustard, or to combined nitrogen mustard and irradiation therapy, were almost entirely confined to the lymph nodes and spleen. Lesions of other organs showed little or no response. In 6 of the 7 cases in which pulmonary lesions were present, the therapy had no effect on these lesions, but in the remaining case a combination of nitrogen mustard and roentgen therapy produced moderate improvement in extensive pulmonary lesions after two previous courses of nitrogen mustard alone had been without effect. At the end of fifteen weeks these lesions again progressed and did not respond to further therapy of the combined type.

The skeleton was involved in 3 cases. Regression of the lesions did not occur in any of these cases as a result of therapy. In 2 of these cases, the lesions progressed during the period of observation.

There was clinical evidence of involvement of the liver in 2 cases. The therapy did not produce any improvement in 1 of these cases. In the other case, the first course of nitrogen mustard produced a significant decrease in the size of the liver, which lasted for six weeks. The enlargement recurred at the end of this period and was not relieved by subsequent courses of nitrogen mustard.

In 6 cases, the erythrocyte count was less than 3,500,000 per cubic millimeter of blood. Leukopenia was present in 2 cases in which the anemia was severe. In these cases, the leukocyte count was less than 2,800 per cubic millimeter of blood. Nitrogen mustard, administered alone or in combination with roentgen rays, did not produce any significant improvement in the anemia or leukopenia in any of these cases. Blood transfusions also were used in some cases, but they likewise did not produce any improvement.

Lymphosarcoma.—Table 2 shows the results of nitrogen mustard in 10 cases of lymphosarcoma. The duration of the disease prior to the institution of nitrogen mustard therapy ranged from 4 to 52 months and averaged 17.6 months. In 6 cases, death occurred from progression of the disease. In these cases, the duration of life after the institution of nitrogen mustard therapy ranged from 1 to 6 months and averaged 3.5 months.

In case 21, the response to nitrogen mustard therapy was more rapid and more complete than it was in any of the other cases of lymphosarcoma. The patient had not been treated previously. Evidence of enlargement of the lymph nodes, spleen and liver disappeared within one week after the administration of nitrogen mustard was begun. The clinical remission lasted for 2.5 months. Enlargement of the spleen and of some of the lymph nodes recurred at the end of this period. In case 24, evaluation of therapy was based on symptoms alone, as the disease was confined to retroperitoneal lymph nodes. There were no physical observations, and the diagnosis was established by laparotomy and biopsy. Abdominal pain of incapacitating degree was the only symptom. This was relieved completely for 4.5 months by the initial course of nitrogen mustard. The pain recurred at the end of this period.

In case 25, enlargement of the spleen and enlargement of the liver were the principal physical observations. Remission could not be considered complete because, despite a decided decrease in the size of these organs as a result of therapy, their size still did not approach normal. Enlargement recurred at the end of six months. In this case, partial remission is to be compared with a partial remission of similar degree which lasted twelve months and was produced by the initial therapy, which consisted of a series of applications of roentgen rays.

Mycosis Fungoides.—Our initial experience with nitrogen mustard in the treatment of mycosis fungoides at the Mayo Clinic has been reported previously.[3] Since the publication of this report, several other patients with mycosis fungoides have been treated. Our knowledge of the value of nitrogen mustard in this disease, however, has not increased to the point where new or more definite conclusions are warranted. The following statements may be made, on the basis of our experience to date. When lesions of mycosis fungoides respond favorably to nitrogen mustard, the effect is apparently identical with that of roentgen rays. The effectiveness of nitrogen mustard therapy tends to diminish with repeated courses. In this disease, development of resistance to roentgen therapy constitutes an indication for a trial of nitrogen mustard, for two reasons. First, further remissions sometimes can be produced by nitrogen mustard. Second, sensitivity of the lesions to roentgen rays may return after the patient has been treated for weeks or months with nitrogen mustard. By thus alternating the two forms of therapy, it is sometimes possible to maintain the patient in relative comfort for a period considerably longer than would be possible by using roentgen rays

TABLE 2.—*Results of Therapy in 10 Cases of Lymphosarcoma*

				Response to Therapy †

3. Kierland, R. R.; Watkins, C. H., and Shullenberger, C. C.: The Use of Nitrogen Mustard in the Treatment of Mycosis Fungoides, J. Invest. Dermat. 9: 195-201 (Oct.) 1947.

alone. Microscopic examination of lesions of mycosis fungoides before and after the use of nitrogen mustard reveals that the number of cells constituting the infiltrate in these lesions may be diminished as a result of this therapy, but the histologic picture of mycosis fungoides is still evident in the specimens obtained after treatment. More work of this kind should be done.

Cutaneous Lymphoblastoma.—We have treated 1 patient, a woman aged 41 years, who had suffered for a year from two erythematous infiltrating lesions of the skin of the face, associated with severe pruritus. A specimen of one of the lesions was examined microscopically three months after the onset, and the histologic picture was characteristic of lymphoblastoma. The patient exhibited no other evidences of lymphoblastoma. Two courses of roentgen therapy failed to prevent progression in the size of the lesions. A course of nitrogen mustard was then given. This promptly relieved the pruritus and caused the lesions to regress completely in the next three months. Follow-up data, which were obtained at the end of five months, revealed that the patient was entirely well and had not had any recurrence.

Leukemic Reticuloendotheliosis.—Two patients who had leukemic [illegible] were treated with nitrogen mustard. One of these, a man aged 59 years, died twenty-five days after the completion of the therapy. A clinical picture of granulocytopenia developed before the patient died. The other patient was a man aged 75 years who had had severe cutaneous manifestations of reticuloendotheliosis for three years. The blood picture was characteristic. The patient had not had any previous roentgen therapy, and he was not benefited in any way by a course of nitrogen mustard.

Malignant Neoplasms.—In 7 cases of malignant neoplasms of various types, nitrogen mustard therapy was used because all other therapeutic measures were deemed impossible or inadvisable. The clinical data in these cases are summarized in table 3.

Polycythemia Vera.—The obviously profound effect which nitrogen mustard exerts on the bone marrow naturally suggests its use in the attempt to control polycythemia vera. Jacobson and others[1b] have reported remissions lasting up to 12 months as a result of nitrogen mustard therapy. Despite some excellent results which have been obtained in the treatment of this disease with radiophosphorus, Hall and one of us (C. H. W.)[4] have expressed the opinion that the incidence of acute leukemia among the patients treated with this agent may be disturbingly high. This constitutes another reason for evaluation of the therapeutic potentiality of nitrogen mustard in this disease.

To date, we have employed nitrogen mustard therapy in 8 cases of polycythemia vera. A protracted follow-up period will be necessary before the results of this therapy can be evaluated and compared with those obtained with other methods of treatment. At this time, our experience may be summarized as follows: One patient obtained complete symptomatic and hematologic remission for 13 months after one course of nitrogen mustard. Three other patients have reported normal blood cell counts and absence of symptoms between 2 and 3 months after the initial courses. Two patients have reported hematologic and symptomatic relapses between 2 and 3 months after their initial therapy, and 1 of them has received a second course. Follow-up data in the other 2 cases are not available at this time.

We believe that the initial results are sufficiently encouraging to warrant further investigation of the usefulness of nitrogen mustard in the treatment of polycythemia vera.

TABLE 3.—*Results of Therapy in 7 Cases of Malignant Neoplasms**

Case	Site of Tumor	Histologic Diagnosis	Duration †	Courses of Nitrogen Mustard	Response	Period of Observation ‡	Clinical Results
29	Bronchus	Squamous cell carcinoma, grade 4	16 mo.	1	None	6 weeks	Condition of patient deteriorated; carcinoma cells in sputum 6 weeks after treatment
30	Bronchus	Carcinoma cells present in sputum	10 mo.	2	None	6 mo.	Died of progression of disease
31	Breast; metastatic involvement of cervical and supraclavicular lymph nodes	Adenocarcinoma	12 mo.	3	None	6 mo.	Disease progressed
32	Esophagus	Probably adenocarcinoma, grade 4	5 weeks	1	None	2 mo.	Died of progression of disease
33	Bronchus	"High grade carcinoma"	4 mo.	1	Partial relief of obstructive symptoms for 4 weeks	4 mo.	Died of progression of disease
34	Primary site undetermined; metastatic involvement of supraclavicular and inguinal lymph nodes	Adenocarcinoma, grade 4	2 mo.	1	Subsequent use of nitrogen mustard or irradiation (elsewhere) did not produce any improvement	4 mo.	Died of progression of disease
35	Rectovesical space; metastatic involvement of liver, pancreas, lungs and skeletal muscles	Fibrosarcoma	16 mo.	1	None	5 weeks	Died of progression of disease

UNTOWARD EFFECTS OF NITROGEN MUSTARD THERAPY

It is apparent that the accepted therapeutic dose of nitrogen mustard, while safe for the large majority of patients, may be severely toxic for some. It must become obvious to the physician who employs this agent frequently that the hemopoietic tissues of some patients are unusually sensitive to the action of this drug. Unfortunately, one cannot predict which patients are likely not to tolerate it. Among the patients with Hodgkin's disease whom we have treated were a few who exhibited anemia, leukopenia and thrombopenia prior to the institution of nitrogen mustard therapy. The use of this agent did not have any obviously severe effect on the blood cell counts of these patients. On the other hand, in a few cases in which the patients had normal erythrocyte, leukocyte and thrombocyte counts before nitrogen mustard therapy was begun, suppression of bone marrow activity reached such degree in the second to fourth week after the last injection of nitrogen mustard that neutrophil and thrombocyte counts reached levels at which serious complications may arise.

---

[4] Hall, B. E., and Watkins, C. H.: The Medical Use of Radioactive Isotopes: Radioactive Isotopes in Hematologic Disturbances and Neoplasms, Am. J. M. Sc. 213: 621-628 (May) 1947.

We have observed a case in which a clinical and hematologic picture of granulocytopenia with associated purpura developed within ten days after the completion of a course of nitrogen mustard therapy. The blood smears did not reveal any neutrophils and only a few thrombocytes were seen. In 2 other cases in which the usual calculated dose of nitrogen mustard was administered, severe thrombopenia, purpura and intrapulmonary bleeding developed in the third week after therapy. In 1 of these cases, clinical evidence of intracerebral bleeding also occurred. While the nature of the diseases for which nitrogen mustard therapy was instituted in these cases was such that the drug could not be unequivocally incriminated as the cause of these complications, the relationship, in time, of its administration to the clinical deterioration was suggestive. It appears that the use of nitrogen mustard carries a risk; therefore, in employing it, the physician should weigh the seriousness of the existing disease against that of the possible complications arising from the therapy and should recognize that the month following the completion of therapy is a potentially dangerous period during which severe neutropenia or thrombopenia may occur.

SUMMARY AND CONCLUSIONS

This paper includes an analysis of the results of nitrogen mustard therapy, or combined nitrogen mustard and irradiation therapy, in 18 cases of advanced Hodgkin's disease. Our experience indicates that, in cases in which the disease has become more or less refractory to roentgen therapy, nitrogen mustard has very limited usefulness as an agent which may produce transient subjective improvement without necessarily altering or significantly delaying the progressive course of the disease. It is apparent that existing lesions may progress or that new lesions may develop within a few weeks to a few months after institution of nitrogen mustard therapy. Very satisfactory regression of some of the lesions in a given case may occur as a result of this therapy, while progression of other lesions is taking place simultaneously. Lesions which involved nonlymphoid organs responded poorly or not at all to this therapy. Our results suggest that the cases in which there was the least tendency to progression during the period of observation were those in which the disease had existed for the longest time prior to the institution of nitrogen mustard therapy.

The results of nitrogen mustard therapy in 10 cases of lymphosarcoma also have been considered. While the over-all results were not encouraging, in our experience they were unpredictable. While 7 of 10 patients either died within six months or were unimproved after this therapy, it appears that some patients may respond very well to it. From our experience, we cannot draw any conclusions as to the correlation between the histologic pattern in a given case of lymphosarcoma and the responsiveness to therapy.

In our hands, nitrogen mustard has been a valuable adjunct to roentgen rays in the treatment of mycosis fungoides, although its usefulness varies in different cases. A very satisfactory result was obtained with nitrogen mustard therapy in a case of cutaneous lymphoblastoma after irradiation had failed to stop progression of the disease.[5] Initial results in the treatment of polycythemia vera with nitrogen mustard have been sufficiently encouraging to warrant further investigation of its usefulness in this disease. Malignant neoplasms have responded very poorly or not at all to nitrogen mustard therapy, in our experience.

Nitrogen mustard is potentially a dangerous drug and is capable of severely damaging the hemopoietic tissues when used in the presently accepted therapeutic doses. Finally, we believe that a true evaluation of the efficacy and reliability of nitrogen mustard in cases of lymphoblastoma can be determined only by employing this agent alone in a series of hitherto untreated patients and comparing the results with those obtained in treating similar patients with irradiation and with a combination of irradiation and nitrogen mustard.

Clinical Notes, Suggestions and New Instruments

DEATH DUE TO PHENOL CONTAINED IN FOILLE®

Report of a Case

THOMAS D. CRONIN, M.D.
and
RAYMOND O. BRAUER, M.D.
Houston, Texas

A 10 year old white boy was accidentally burned early on a Saturday evening when kerosene was thrown on a fire. He sustained first and second degree burns of the face; anterior part of the neck, chest and abdomen as far as the umbilicus; arms, and a 12 by 9 cm. area on the right thigh, or approximately 25 to 30 per cent of the body surface. The results of the rest of the physical examination were essentially negative.

He was taken immediately to the hospital emergency room and given 500 cc. of plasma and morphine sulfate, ⅙ grain (11 mg.).

The burned areas were clean, so that superficial debridement was carried out after he had responded from the initial shock. A pressure dressing was applied, which was saturated with foille® (a preparation containing phenol, Carbisulphoil Company),[1] and he was admitted to the hospital at 10 p. m. Saturday night.

In the original application, about 2,500 cc. of foille® emulsion was applied, and the nurses were instructed to apply it as often as necessary to keep the dressing moist. They were rather diligent in carrying out this order, so that during the two and a half days the patient lived after he had been burned, more than 7,500 cc. of the preparation was used.

His initial blood test showed 5,680,000 red blood cells, 16.0 Gm. (104 per cent) of hemoglobin and 20,000 white blood cells, with 9 per cent lymphocytes and 91 per cent neutrophils.

---

[5] Since preparing this report, we have employed nitrogen mustard in treating another patient with very widespread cutaneous lymphoblastoma, who had had no previous roentgen therapy. Very remarkable clinical and histologic improvement was apparent three months after the completion of the therapy.

[1] The contents are given in detail later in the paper.

He was given penicillin, 30,000 units every three hours, and during the next twenty-four hours he received a total of 1,500 cc. of plasma, 2,500 cc. of dextrose in isotonic sodium chloride solution and more than 600 cc. of water orally, for a total fluid intake of 4,600 cc. The urinary output was about 500 cc. He vomited a small amount of greenish fluid five times and a large amount of clear fluid twice. During the rest of the night, he required nothing for pain, was "mentally clear" and slept well, awaking occasionally for water. The respirations remained about 20 and pulse rate 104 to 116.

By Sunday noon his temperature had risen from 102 to 104 F. rectally after a slight chill. He required codeine, ½ grain (33 mg.), at 10 a. m., pantopon® (an opium preparation containing the total opium alkaloids in the form of soluble hydrochlorides), ⅙ grain (11 mg.), at 1 p. m., and pentobarbital sodium at 1:30 p. m., as he had been "crying and screaming." For the next six hours, he was quiet and slept at intervals, but by 10 p. m., Sunday night, he was very restless and crying again. His temperature had dropped to 100.8 F. and his pulse rate to 100. A hemoglobin determination at this time was reported as 13.0 Gm., or 84 per cent.

During the rest of the night, which was the beginning of his second hospital day, he required pentobarbital sodium, 1 grain (65 mg.), twice and pantopon,® ⅙ grain (11 mg.), once. By 4 a. m. he was complaining of severe intermittent abdominal pain and expelled flatus frequently. In spite of all this, the nurses said that he had a fair night and roused little when given his 6 a. m. dose of penicillin.

On Monday morning it was noticed that his abdomen was distended, but it was difficult to make a satisfactory examination because of the burn. The distention was treated with enemas and a rectal tube inserted, with returns of a dark brown liquid and considerable flatus.

His fluid intake during Sunday night and Monday, his second hospital day, was 500 cc. of blood, 1,750 cc. of dextrose, 750 cc. of plasma and over 170 cc. of water, for a twenty-four hour fluid intake of 3,170 cc. This twenty-four hour output was unknown. At 10:30 p. m. Sunday, beginning his second day, it was first noticed that his urine was very dark. After this, he passed three similar specimens, one of which amounted to 240 cc. The final eight hours of this day he put out no urine. He had lost some fluid through the rectal tube and Wangensteen suction apparatus, the latter having been put in place early Monday evening. Shortly after the suction was begun, he was given a sodium bicarbonate enema, with highly colored returns, containing no fecal material.

During this second twenty-four hour period he had repeated blood cell counts. The hemoglobin at 7:30 a. m. was 14.5 Gm. (94 per cent); in the early evening it was 12.5 Gm. (81 per cent), and at 7 p. m. it was 13.0 Gm. (84 per cent). The hematocrit reading in the afternoon was 37 per cent. More complete studies were not done, because of the technical difficulties involved in getting the blood.

We first saw him in consultation on Monday at noon. At this time, he had a cannula tied in the left saphenous vein, the abdomen was distended and he was in a stuporous condition. It was believed wise not to disturb the dressings, but concentrate on giving him the blood and plasma he was then receiving. His lethargy was partially attributed to the pantopon® which he had received forty-five minutes before.

We saw him four hours later, at which time his temperature had risen to 101 F. and he was still stuporous, seemingly out of proportion to the condition to be expected from the burns alone. All treatment with narcotics had been stopped after our first visit. Shortly before this, he became rather cyanotic and nasal oxygen therapy was begun. It was now that it seemed to us that part of the odor of the foille® was that characteristic of phenol.

A pharmacist was called, who stated that foille® contained 2 per cent or more phenol. The dressings were removed and replaced with a petrolatum gauze pressure dressing. It was noticed that all the burned surfaces had a white parchment appearance, with little or no serous oozing from the surface. This dressing change was accomplished without anesthesia and with no resistance from the patient.

Late Monday night and early Tuesday morning (which was the beginning of his third day) his respirations became noisy and labored, with gurgling sounds in the trachea. Suction of the mucus was required to maintain the airway. There were also many moist musical rales. The mucus increased and later became foamy and pink tinged.

During the patient's final seventeen hours his output was 1,100 cc. of dark urine. He lost 240 cc. of a dark brown liquid through the Wangensteen tube. His intake, meanwhile, amounted to 500 cc. of blood, 1,500 cc. of dextrose in isotonic sodium chloride solution and over 75 cc. of water, for a total fluid intake of 2,075 cc.

By early Tuesday morning he was comatose, with grunting irregular respirations; the temperature had increased to 103.4 F. and the pulse rate to 134. His condition remained about the same until about 2 p. m. Tuesday, when the respirations became rather shallow and rapid and his pulse weak. He died at 3:15 p. m.

Postmortem Examination.—Postmortem examination revealed a superficial burn over the areas previously described, with decided edema of the face and neck. The pleural, pericardial and peritoneal cavities were smooth and glistening, with some straw-colored fluid in the pericardial cavity. The lungs showed spotty, firm, dark brown and reddish areas, especially in the lower lobes; microscopic examination showed hypostatic pneumonia. The trachea and bronchi contained mucus, and the mucosal lining was hemorrhagic.

The spleen was grossly normal, but microscopically showed acute congestion. The adrenal glands, heart and aorta were essentially normal. The liver grossly was light brown, firm in consistency and about normal size. On sectioning, the cut surfaces were light brown, but the liver markings were not as clear as normal. Microscopically, it showed a midzonal necrosis, involving almost all the liver lobules with complete destruction of the involved cells.

The kidneys were normal in size. The capsules stripped with ease, revealing pinkish red surfaces. On sectioning, the demarcation line between cortex and medulla was visible. Microscopically, the glomeruli were normal, but the epithelial cells lining the tubules showed decided parenchymatous degeneration with loss of the cellular configuration.

The digestive tract showed acute congestion.

Chemical studies were made by Henry O. Nicholas, Ph.D., Associate Professor of Chemistry, Rice Institute. He reported the following observations: a total volume of urine of 220 cc., a trace of free volatile phenols and 22 mg. of conjugated phenols per hundred cubic centimeters of urine. The total volume of gastric juice was 18 cc., with a trace of free volatile phenols and 18 mg. of conjugated phenols per hundred cubic centimeters of gastric juice. The results of tests of mixed tissues (liver, stomach wall, kidney, qualitative tests only) were strongly positive for both free and volatile phenol. In the analysis of foille® for phenol, one method showed the presence of 1.4 per cent phenol by weight and another method showed the presence of 1.8 per cent phenol by weight.

In reviewing this case, it would seem that the pathologic process was probably already fixed by the time we saw him, as 7,500 cc. of the foille® (105 to 147 Gm. of phenol, depending on whether 1.4 per cent, the lowest figure of Nicholas, or 1.97 per cent, the Carbisulphoil Company figure, is used) had already been applied to the dressings.

The damage to the kidneys was apparent within twenty-four hours of the application of the foille,® as a urine specimen was reported as having a dark color as early as 10:30 p. m. Sunday night. The patient passed three other dark specimens during the following sixteen hours, after which he put out no urine for nine and a half hours. After this period of anuria, the output was greater than it had ever been, almost equaling the intake for this period, when previously the output had always been small compared with the intake.

The initial study of the blood showed hemoconcentration, but later studies did not, as would have been expected if the fatal outcome was due to the burn alone. In our experience, the stuporous condition noted in this patient was out of proportion to the extent of the burn.

OTHER REPORTS

Johnstone[2] reported a case of a 22 year old man who accidentally spilled a bottle of carbolic acid, saturating the "right leg, right side of the abdomen and the chest." Fellow employees immediately removed his shirt and threw water over the upper part of his body. He then walked across the street to a physician's office without difficulty, but collapsed and died within fifteen minutes of his arrival. Autopsy revealed, in addition to the local first and second degree burns, "hyperemia and edema of the lower lobes of both lungs, and marked hyperemia and edema of both kidneys, pancreas and spleen. There was no change in the heart or liver. Analysis of portions of the pancreas, spleen and kidneys was positive for carbolic acid, and the chemist reported the quantity found was increased five times over that usually found in these tissues at autopsy."

Thienes and Haley[3] said, regarding the toxic dose, ". . . 5 grs. of phenol or creosol or 1 cc. creosote may cause dangerous symptoms. Three grams of any one may be fatal although recovery after 150 cc. of creosol has occurred." Gonzales, Vance and Helpen[4] stated, ". . . the fatal dose of phenol is about one-half ounce when it is taken by mouth. . . . When used in wounds or body cavities, a small dose can be quite dangerous. The average duration of the clinical course in a fatal case is from two to twelve hours, but may be shorter or longer."

The symptoms of poisoning are "dizziness, delirium, sometimes convulsions, collapse and loss of consciousness, fall of temperature (or sometimes fever), labored breathing and oliguria with dark urine."[3] The dark urine is an early symptom of mild poisoning. Cases of delayed death show symptoms of renal necrosis—oliguria or anuria, albuminuria, hematuria, edema and retention of waste products in the blood. The odor of phenol is noticeable on the breath.

Phenol is detoxified by the liver after absorption and is excreted by the kidneys as ethereal sulfates, hydroquinol or pyrocatechol, glucuronates and free phenol. A trace is excreted by the lungs. It produces cerebral edema and cardiac dilatation. If life persists for one-half hour or more, there is glomerular and tubular degeneration of the kidneys with central necrosis of the liver.

The diagnosis is made by the histologic picture of the liver and kidneys together with the chemical analyses. "Phenols may be demonstrated in suspected bottles, in stomach washings or in urine. At autopsy the odor may be detected, even before opening the stomach."[3]

The cause of early death is due to shock, respiratory failure or cardiac collapse. Delayed death is of renal or hepatic origin.

In 1941, the Council on Pharmacy and Chemistry[5] reported on foille® at the request of the Carbisulphoil Company of Dallas, Texas. The product was submitted as a "new protective antiseptic and analgesic dressing in the local treatment of recent and infected burns, traumatic and infected wounds and indolent ulcers." It was stated to consist of the following ingredients:

Alcohol	1.20
Phenol	2.36
Benzocaine [ethyl aminobenzoate]	1.26
Calcium soap	0.36
Calcium iodide	0.24
Potassium iodide	0.12
Oxyquinoline base	0.18
Calcium thiosulfate	0.03
Calcium sulfite	0.07
Calcium sulfate	0.13
Sulfur (free)	0.17
Water	2.85
Corn oil (fixed)	90.33
Glycerine	Present

The manufacturer further claimed: "The benzocaine plus the phenol is said to effect an immediate and pronounced anesthesia which mitigates shock and pain to provide a distinctly favorable factor in the initial stage of a serious burn. The action of the soap augmented by phenol on prolonged contact is claimed to coagulate the serum exudation, excluding air and forming a soft shield."

"In support of claims for the product, the manufacturer submitted . . . additional laboratory statements to show that poisoning from the phenol contained in the product will not occur because it is not appreciably absorbed through the skin because of its affinity for the water-in-corn oil vehicle and that a mild antiseptic action occurs with prolonged application."

In summarizing its report, the Council stated, "The evidence submitted by the firm to support the claims for Foille is largely testimonial, poorly, if at all, controlled and consists of considerable reduplication of material. The case reports submitted are further inadequate from the standpoint of blood studies by which to evaluate the systemic condition of the patients." It went on, "Aside from the question of systemic absorption, the possible danger of local injury to tissues by the action of 2.35 per cent phenol should be considered." The Council voted that foille® be "not accepted for inclusion in New and Nonofficial Remedies because it is marketed under an uninformative proprietary name without satisfactory evidence to establish the therapeutic rationale for its complex formula and the claims made for it."

A brochure furnished by the Carbisulphoil Company states, "In the local treatment of major or minor burns and other wounds, Foille may be used not only for first aid but in the further management of the patient. . . . Dressings saturated with Foille emulsion should be applied directly to the wound and the dressing kept moist with Foille. . . . In some cases, depending upon the clinical picture—temperature, pulse and respiration—it may be appropriate to continue with the original dressings for a longer period of time by frequently saturating them with Foille in order to keep the area moist, soft and pliable. Such treatment may be continued either with or without changing the dressings until healing is complete or until conditions are satisfactory for grafting." The formula listed in the brochure was essentially the same as that given previously, except that the total phenol was stated to be less than 1.97 per cent.

COMMENT

In foregoing quotation, it should be noted that the free use of foille® is advised in both major and minor burns and for unlimited periods. Nowhere in the brochure is there any warning as to the possible danger of absorption of phenol.

We believe that the use of phenol in this mixture is dangerous and, furthermore, is irrational, as burned patients are soon fairly comfortable after the application of bland agents, such as petrolatum. Certainly there is no justification for the continued use of phenol on a burned patient.

We have found no reports of fatalities from the use of foille,® but a sober consideration of the events in this case would indicate that there have probably been other deaths due to the contained phenol. It is probable that in these cases the death has been attributed to the burn itself.

We feel that foille® as now constituted, with approximately 1.97 per cent phenol, is a dangerous and irrational preparation which should be withdrawn from the market immediately.

SUMMARY

A case is presented of a 10 year old boy with 25 to 30 per cent of the body surface burned. The clinical course and chemical and postmortem examinations revealed phenol poisoning due to the absorption of phenol contained in foille® (Carbisulphoil Company), the substance applied as the local dressing.

The toxicologic aspect of phenol poisoning is presented. The product foille® was not acceptable to the Council on Pharmacy and Chemistry Aug. 2, 1941. The use of phenol (1.97 per cent) in foille® should be discontinued, as fatal intoxication may result.

Council on Pharmacy and Chemistry

REPORT TO THE COUNCIL

The Council has authorized publication of the following report.
Austin Smith, M.D., *Secretary.*

A STATUS REPORT ON ANALEPTICS

JAMES E. ECKENHOFF, M.D.
With the Assistance of
CARL F. SCHMIDT, M.D.
ROBERT D. DRIPPS, M.D.
and
SEYMOUR S. KETY, M.D.
Philadelphia

Although knowledge about the nature of the changes which analeptics[1] produce in cells is almost totally lacking, the drugs now in use as analeptics fall into four convenient categories:

1. Those which have a primary stimulant action on the nervous system and the value of which depends on that action. The representatives of this group are picrotoxin, metrazol® (pentamethylenetetrazol), nikethamide (coramine®), strychnine, caffeine and atropine; the latter three may be regarded as obsolescent or (particularly atropine) obsolete for analeptic purposes.

2. Drugs the analeptic effects of which are due to reflexes from one source or another. The most powerful of such reflexes are those from the carotid and aortic bodies. Alpha lobeline owes its therapeutic action to the stimulation of these structures. Cyanides, sulfides and nicotine are capable of similar actions but are not used because of their extremely toxic properties and connotations. Irritants of the nose, mouth and stomach (smelling salts, aromatic spirits of ammonia, whiskey, brandy) belong in this category, as do subcutaneous injections of camphor, alcohol or ether and any type of chemical or physical intervention capable of arousing sensory impulses which bombard the central nervous system (e. g. slapping, walking).

3. Drugs which stimulate both the central nervous and cardiovascular systems and which, in sufficient dosage, produce not only convulsions but also hypertension and tachycardia. Their analeptic effects presumably depend not only on the direct stimulation of nerve cells (as with group 1), but also an increase in the blood supply to the brain. This group includes practically all of the aromatic sympathomimetic amines, but for this purpose those in which the central nervous stimulant action is relatively great and the sympathomimetic effect relatively small are preferred to those in which the opposite relationship exists. Thus amphetamine (benzedrine®), d-amphetamine (dexedrine®) and desoxyephedrine (methedrine®) are preferable analeptics to epinephrine, paredrine® (*p*-hydroxy-*a* methyl-phenyl-ethylamine) or phenylephrine hydrochloride (neo-synephrine hydrochloride®), with ephedrine in an intermediate position. Aliphatic pressor amines, 2-aminoheptane sulfate (tuamine sulfate®) and methylamino-iso-octene (octin hydrochloride®); imidazole pressor derivatives, like naphazoline hydrochloride (privine hydrochloride®), and special agents, like posterior pituitary and ergot derivatives, do not stimulate the central nervous system sufficiently to be useful in this connection.

4. Substances which exert a specific stimulant effect on nerve tissue by entering directly into the biochemical reactions on which the excitability of this tissue depends. These include intermediate products of carbohydrate metabolism, such as pyruvate, succinate and fumarate as well as the components of the vitamin B complex.

Analeptics have not proved to be infallible when used in the treatment of central nervous system depressions. This may mean that the drugs now available for this purpose are deficient in important respects and that intensive search is indicated for other agents which would produce superior clinical results, or it may mean that the available analeptics are capable of doing practically everything that can reasonably be expected of drugs of this type. If the second of these is true, further improvement in the management of the unconscious patient would depend on other measures based on a better knowledge of the underlying derangements.

In an attempt to assess the present status of analeptics a most important consideration becomes an understanding of what such drugs may be expected to accomplish. This amounts to an inquiry into the nature of the changes which underlie unconsciousness or coma, as encountered clinically, and the manner in which analeptics affect these abnormalities. These questions will be considered.

THE CAUSES OF CLINICAL DEPRESSIONS OF THE CENTRAL NERVOUS SYSTEM

The common underlying mechanism in all severe depressions of the central nervous system appears to be an interference with the complex metabolism of nerve tissue. The integrity of this metabolic process depends on at least two conditions. The first of these is the homeostasis of the cellular environment, a term which Cannon used to characterize the maintenance of a constant and optimal concentration of available oxygen and glucose, of carbon dioxide and hydrogen ion and a host of other substances. This homeostasis is achieved only by a well integrated functioning of the cardiovascular, respiratory, assimilative and excretory mechanisms of the organism. In addition to an optimum cellular environment, there must be present, for a normally functioning central nervous system, certain intracellular mechanisms for the proper conversion of energy. These two conditions may serve as a basis for a classification of the relatively acute depressions with which this discussion is concerned. Such a classification is important and even urgent if rational therapy is to be achieved.

CLASSIFICATION OF ACUTE CENTRAL NERVOUS SYSTEM DEPRESSION

A. Failure of homeostasis
  1. Changes in composition of arterial blood
    (*a*) Lack of available oxygen and/or accumulation of carbon dioxide (respiratory disease, depression or cessation)
    (*b*) Lack of available nutrient material (glucose primarily)
  2. Failure in cerebral circulation
    (*a*) General circulatory derangements (heart failure, asystole, decreased blood volume, loss of vasomotor tone—all characterized by a low systemic blood pressure)
    (*b*) Local circulatory disturbances (increased intracranial pressure, cerebral arterial spasm, occlusion or rupture)

From the Department of Anesthesiology, Harrison Department of Surgical Research and Department of Pharmacology, School of Medicine, University of Pennsylvania.

[1] An analeptic may be defined as a drug capable of stimulating the normal central nervous system and which is used for the purpose of overcoming a depression of that system.

B. Failure in intracellular metabolism
  1. Lack or destruction of certain intracellular enzyme systems (deficiency diseases, "irreversible" stage of other depressions)
  2. Action of noxious substances
    (*a*) Endogenous—acidosis, ketosis, uremia
    (*b*) Exogenous—narcotic or other drugs

Most clinical depressions involve more than one of the causes listed, either from the start or as subsequent complications. From the point of view of the present discussion, there is little doubt that depressions caused by narcotic drugs are the most amenable to analeptic drugs. Other depressions are less likely to be helped and may indeed be intensified by analeptic therapy, particularly if such therapy is followed by convulsions.

THE MECHANISM OF ANALEPTIC ACTION

Since analeptics are most effective in the presence of a narcotic depression, it is probable that the actions of the two types of drugs are intimately related. The more probable relationships are: (1) direct chemical inactivation or neutralization of the narcotic by the analeptic, (2) diminution in the effective concentration of the narcotic agent within the nerve cell and (3) physiologic antagonism, i. e., increased excitability of nerve cells overshadowing a continuing depressant effect.

There is no evidence that would indicate a direct inactivation of a depressant drug by an analeptic agent, either *in vitro* or *in vivo*. In view of the diverse chemical and physical properties of narcotics and analeptics, it would indeed be surprising if a common reaction were demonstrated.

A rational and simple explanation of the mechanism of action of analeptics would be a diminution in the effective concentration of the depressant in nerve cells brought about by displacement of the narcotic from combination with neuronal protoplasm or by promotion of its excretion or detoxification. The displacement theory is supported by the evidence that picrotoxin stimulates breathing only when respiration is depressed, and then as part of a general awakening from narcosis. These phenomena are, however, peculiar only to certain depressants (phenobarbital with morphine, chlorobutanol, paraldehyde and tribromoethanol solution [solution avertin with amylene hydrate®]) and to picrotoxin as the stimulant; they have not been seen when metrazol, caffeine or nikethamide was used to counteract these same narcotics or when picrotoxin was used against depressions caused by urethane or ethyl alcohol, and, finally, they apparently are seen only in light or moderate depressions but not in deep narcosis.

If the displacement theory is correct, the concentration of narcotic in the cerebral venous blood should rise and that in nervous tissue should fall when the analeptic effect is at its height. There are as yet no data concerning this phase of the problem. Concentrations of paraldehyde, avertin® and barbiturate in *systemic* venous blood have not been significantly altered by the administration of analeptics, but this would not preclude a concomitant mobilization of the narcotic from the brain and deposition in other tissue. The methods for quantitatively estimating the barbiturate content of tissues and blood have been too inaccurate to warrant confidence in the observations, but the recently described spectrophotometric procedure may make possible a definitive answer to this question.

According to the published evidence, physiologic antagonism is the most probable explanation for the reciprocal relationship between analeptics and depressants. In favorable circumstances the antagonism may be so nearly perfect that a mixture of a narcotic and an analeptic can be injected intravenously with surprisingly little effect, although the amount of each agent is such that coma or convulsions would occur if it were given alone. Similarly, a dose of barbiturate which would otherwise be fatal will cause only a depression if given with an analeptic; respiratory failure produced by intracisternal injection of a barbiturate can be counteracted by a similar prompt injection of picrotoxin, and the stupor produced by certain barbiturates may often be instantly terminated by intravenous injection of a suitable analeptic in laboratory animals or in human subjects.

The explanation of this antagonism depends on knowledge of the cause of the narcotic depression, which is still obscure. The older physicochemical conceptions of narcosis, such as the lipid, surface tension and adsorption theories, have ceased to attract attention or stimulate fundamental research, largely because recent discoveries of the complex biochemical relations existing in even the simplest cells have rendered unlikely a simple all-inclusive explanation for all of the observed phenomena of narcosis. One of the recent trends has been a revival of the idea formulated originally by Verworn, viz., the fundamental feature in the narcotic process is interference with oxidative reactions on which cell functions depend. Quastel and his associates were able to show a consistent depression of the uptake of oxygen by nerve tissue in vitro in the presence of concentrations of narcotics within a range compatible with life. In the monkey's brain *in vivo* oxygen consumption was found to be depressed by narcotics and elevated by analeptics, the changes in oxygen uptake showing a close parallelism to the concomitant changes in functional activity. A limited amount of recent evidence indicates that the same parallelism exists in human beings in different physiologic and pathologic states. There are data to indicate that narcotics interfere with the dehydrogenating enzymes rather than those directly concerned with oxygen; this is shown by the fact that under the influence of narcotics cytochrome C can take up oxygen in a normal manner but cannot release it again.

The opposing action of analeptics has not been studied from the point of view of anything but over-all activity or oxygen uptake. Conceivably analeptics might: (1) specifically displace narcotics from their combination with cell dehydrogenases, (2) serve as coenzymes or specific substrates which would permit normal or hypernormal cell oxidations in spite of the narcotic, (3) combine with neuronal protoplasm in some manner unrelated to the narcotic but capable of overpowering its effects or (4) set up nerve impulses sufficiently strong to produce the latter type of result. Choice among these is a matter of individual preference until the underlying mechanisms are better understood.

An interesting variation of this conception of physiologic antagonism has to do with the effects of narcotics and analeptics on synaptic transmission. Dripps and Larrabee have observed that barbiturates will depress this process if used in greater than anesthetic doses and that metrazol® could counteract the depression and cause facilitation. This cannot be made the basis for a general explanation of analeptic action, however, because picrotoxin does not affect synaptic transmission and nikethamide only depresses it.

From the foregoing discussion, it becomes apparent that the mechanism of action of analeptics has not been clearly elucidated but that current evidence favors the theory of physiologic antagonism. It should be understood that other possible mechanisms of action are excluded only because of the lack of positive evidence. Final clarification of the mechanism of action of analeptics must await some or all of the following: (*a*) development of an acceptable method for quantitative determination of a barbiturate in body fluids, (*b*) the planning and execution of carefully controlled experiments designed to measure the normal deposition and removal of narcotics in tissue and the influence of analeptics on such deposition and removal and (*c*) further information on the mechanism of narcotic depression.

EVALUATION OF INDIVIDUAL ANALEPTIC AGENTS

In evaluating individual analeptics, the following facts must be recognized: (*a*) Patients have recovered from more than usually fatal doses of barbiturate without the benefit of an analeptic; (*b*) there are definite hazards in the use of analeptics for the treatment of depressant states, and (*c*) no analeptic can be depended on to cause the recovery of a patient deeply depressed from a usually fatal dose of a barbiturate.

Much of the difficulty in obtaining significant data for the evaluation of analeptics is due to the wide variability in the response of human beings or animals to the same dose of a barbiturate. The minimum lethal dose of a given barbiturate may vary widely in different groups of the same species of animals or may change in the same group with the season of the year. In patients additional factors play a part in determining this variability. These include: the degree of absorption of a given dose of drug, the presence of coexistent disease, the age and physical status of the patient and the period between ingestion of the drug and onset of treatment. For the evaluation of the effectiveness of analeptics, these factors and others to be elucidated in this report must be taken into consideration. To one examining the literature critically, it becomes apparent that, in spite of the large number of reports, those containing complete or incontrovertible data are relatively few. The outstanding deficiencies of many of the existing reports are: a lack of adequate controls, the fact that conclusions have been drawn on very small numbers of experiments, the inability of one group to duplicate the observations of another and the use of experimental methods which are difficult of interpretation. Another distinct impression is that many investigators have attempted to draw conclusions on the basis of inadequate dosages of the analeptics. The following paragraphs summarize the data that are generally accepted, except for the reservations mentioned, for the use of individual analeptics.

Picrotoxin.—In 1936 and again in 1939, the Council on Pharmacy and Chemistry published reports on the use of picrotoxin as an analeptic agent. These reports cautioned that picrotoxin had not been fully evaluated and should be used only by those fully aware of its potentialities. The laboratory data available today suggest that picrotoxin is the most potent analeptic agent for use in treating barbiturate depression, but the published clinical data do not offer completely convincing proof that this drug is the drug of choice for analeptic use against all narcotics.

The administration of picrotoxin to normal human beings or animals produces practically no effect until the dose is large enough to produce convulsions. Subconvulsive doses do not affect circulation or respiration or elicit other signs of significant central nervous system stimulation. However, if picrotoxin is given to an animal in which the respiration and circulation have first been depressed by a barbiturate, an increased minute volume of respiration and a rise in blood pressure may be noted. These are the result of direct stimulation of the respiratory and vasomotor centers.

This apparent antagonism between picrotoxin and barbituric acid derivatives has been substantiated by experiments such as the following: 1. Linegar and his co-workers administered intravenously alternate doses of barbital sodium and picrotoxin to rabbits and were able in this manner safely to expose their animals to total doses of the barbiturates which were four times the estimated lethal dose. 2. Picrotoxin and narcotic doses of pentobarbital injected simultaneously into a vein in rabbits caused depression for about 10 minutes only. Coriamyrtin, which is chemically and physiologically similar to picrotoxin, when given simultaneously with the same barbiturate actually prevented the rabbit from being depressed at all. The explanation of the difference in action between these two analeptics lies in the latent time of action of picrotoxin, which may be as long as 10 to 30 minutes, a trait distinguishing it from all other analeptics and complicating its proper clinical administration. 3. Another antagonistic effect of narcotics and depressants was shown by the experiments of Maloney and Tatum. Two dogs were simultaneously given lethal doses of amytal® (5-isoamyl-5-ethylbarbituric acid). One of these dogs was then treated with picrotoxin and the other used as a control. When the control dog died the treated dog was killed, and both were examined at necropsy. The lungs of the control dog revealed a complete obliteration of all alveoli, while the treated dog showed only patchy areas of congestion in the lungs. The difference presumably was due to differences in respiratory and circulatory activity, but a greater number of experiments in this series would have been comforting.

Picrotoxin can cause harm to the patient in several ways. First, it may produce convulsions, which have commonly been reported during the picrotoxin therapy of narcosis. The most important reason for these convulsions is the latent period of 10 to 30 minutes between intravenous injection and onset of the full effect of picrotoxin. If the clinician administering the drug does not wait this full interval before giving subsequent doses, convulsions may occur. Usually there are some premonitory signs of convulsions, but there are reports of convulsions appearing without any warning 30 minutes after picrotoxin was administered. In the event of deep depression it is unwise to attempt a complete arousal, since convulsions may appear before awakening. Should convulsions appear, they will certainly lead to a secondary depression and clinically may have led to the loss of life. In profound depressions, picrotoxin should be administered only to the point where reflexes have returned and blood pressure and respiration are maintained.

The second possibility of harm by pictrotoxin is that it may lead to a depression per se. However, most of the laboratory and clinical reports do not substantiate this conclusion unless the analeptic has been given to the point of convulsions following which a secondary depression has often appeared. One report has appeared in which 2,134 mg. of picrotoxin was used, but a convulsion appeared on the eighth day of treatment which resulted in a secondary depression from which the patient never recovered. Large quantities of picrotoxin have been given to patients with barbiturate poisoning with subsequent recovery without secondary depression (viz., 1,745 and 1,020 mg.).

The duration of action of a single dose of picrotoxin is longer than that of metrazol® or nikethamide, so that in clinical usage the interval between doses should be longest with this drug. Following intravenous administration to dogs and rabbits, 5 mg. per kilogram of body weight leaves the blood so rapidly that in 20 minutes the blood concentration has leveled off and in 2 hours it has become negligible. Apparently all tissues take up the drug, but the exact site of detoxification is unknown. It is known to be detoxified at the rate of 1.5 convulsive doses in 100 minutes in rabbits.

Picrotoxin apparently is not the drug of choice in all depressions. Its relatively delayed action and the consequent difficulty of dose regulation preclude its use in any but deep depressions caused by the barbiturates. It is said to be contraindicated in morphine poisoning, but most of the data have been obtained from animals. Since there are wide species differences in the actions of morphine, data obtained in animal experiments have only limited value in relation to human beings. Picrotoxin has been advocated in poisoning from sodium bromide, but in depressions from other drugs other analeptics have more commonly been recommended.

Metrazol.®—Metrazol® (pentamethylenetetrazol) has generally been found to be a valuable analeptic agent, but according to results of animal experiments it is inferior to picrotoxin in potency. Probably the most important difference between the two drugs is that metrazol® elicits its maximum effect immediately following intravenous injection; the drug is therefore of value in treating the respiratory depression that may follow the intravenous injection of the short-acting or ultra-short-acting barbiturates. Metrazol,® like picrotoxin, has little effect on the respiratory center in the unanesthetized animal, but the stimulating properties on the depressed center have been demonstrated conclusively. There is apparently no remarkable effect on the vasomotor center except when very large doses are injected rapidly. When the drug is injected intravenously there is usually a transient hypotension, probably due to a peripheral vasodilator effect. Richards and Menaker expressed the opinion that metrazol® is more effective on the higher centers than picrotoxin and for this reason have suggested the drug as an adjunct to picrotoxin in profound barbiturate poisoning after the latter drug has maintained the reflexes, blood pressure and respirations without causing arousal. Patients awakened from thiopental sodium anesthesia with intravenously administered metrazol® frequently retch, vomit and become restless, particularly if a large dose of metrazol® has been injected rapidly. One wonders whether patients so aroused from anesthesia are any less a nursing problem than those allowed to "sleep out" their anesthesia.

Although metrazol® acts rapidly, its duration of action is brief and the drug may have to be injected at frequent intervals. There is quick equal distribution in all of the tissues with rapid detoxification, presumably in the liver. Werner and Tatum found that in the rabbit 1.66 convulsant doses were detoxified in 100 minutes. The rapidity with which a patient, awakened from thiopental sodium anesthesia with a single intravenous dose of metrazol,® returns to his former state of coma causes one to suspect that the detoxification rate of rabbits may be slower than in human beings.

Metrazol® has not been uniformly effective against large doses of the longer-acting barbiturates, although some case reports of successful results have appeared. The failure of the drug as an analeptic is too often associated with the use of inadequate initial doses and neglect to repeat as often as needed.

Nikethamide.—All available evidence indicates that nikethamide is definitely inferior to pictrotoxin or metrazol® as an analeptic agent in the treatment of barbiturate and most other depressant states. We are not aware of any comparative study of these three drugs that has claimed superiority for nikethamide. The reports favoring its use are for the most part uncontrolled clinical studies. From this it follows that there is no justification for statements such as "the most useful and reliable drug up to date, particularly where barbiturates are concerned" and "traditional value as an antidote for barbiturate."

There is no indication of a remarkable cerebral stimulant action of nikethamide in a barbitalized animal, and there are numerous reports of a secondary depression without convulsions following the use of the drug. In a number of conrolled experiments in which nikethamide was used to treat a central depression, the incidence of deaths was higher in the treated group than in the controlled group.

Various other unwarranted claims have been made for this drug: 1. It consistently leads to an elevation of blood pressure, a claim apparently based on experiments with rabbits but apparently not true in some other commonly used laboratory animals. Gunther and his associates and Schube were unable to demonstrate more than occasional elevations in blood pressure in normal or in hypotensive patients. 2. The drug has been considered a cardiac tonic and a coronary artery dilator, but there is recent evidence that this is not true. Cardiac efficiency has been shown to decrease with nikethamide, and coronary dilatation apparently occurs only with the use of toxic doses. 3. Nikethamide is frequently considered nontoxic, but, with the ever increasing dosage advocated, the convulsive dose determined for animals (50 mg. per kilogram of body weight) is being approached and exceeded in human beings. The administration of divided doses is not without danger, since the rate of detoxification is slower than with picrotoxin or metrazol® (0.5 convulsive dose detoxified in 100 minutes). This agrees with the observations of Eckenhoff and Hafkenschiel, who found that 60 to 80 mg. per kilogram caused convulsions in 1 of 4 normal dogs, but when the same or decreased dose was repeated in 40 to 90 minutes, 3 of the 4 dogs had convulsions and died in one to two hours. Chakravarti found that if the amount of nikethamide needed to awaken mice was compared with the amount that was lethal, the drug was approximately twice as toxic as picrotoxin or metrazol.® 4. Comroe and Dripps have been unable to demonstrate that nikethamide stimulates the carotid body, an action which might have given it some claim to preference over metrazol® or picrotoxin.

The clinical evidence, however, indicates that nikethamide is helpful in the treatment of mildly depressive states, such as from avertin® and the short-acting barbiturates. Tatum states, ". . . if life is not jeopardized through depression either coramine, caffeine or strychnine may effect arousal." Clinical reports advocate the use of nikethamide for the treatment of morphine depression, and in a series of patients suffering from opium poisoning it was found to be of value in all but the most severe conditions.

Strychnine.—Strychnine has its principal effect on the spinal cord; since most of the central depressants act on the medulla and the higher centers, it follows that strychnine cannot successfully combat these depressions. When it has been tested as an analeptic experimentally it has been found to be inferior to picrotoxin or metrazol.® The only possible rational use strychnine could have in analeptic therapy would be as an adjunct to other analeptics to improve muscle tone, and this seems an insufficient reason for one's continuing its use.

Sympathomimetic Amines.—As mentioned at the beginning of this report, sympathomimetic drugs to be used as analeptics should be those in which the central stimulant action is relatively strong and the peripheral sympathomimetic effect relatively weak; this includes amphetamine (benzedrine®), d-amphetamine (dexedrine®) and desoxyephedrine (methedrine®).

Amphetamine has been used in the treatment of psychic depressant states, but the drug has not been tested sufficiently to warrant definitive statements as to its efficacy in narcotic depressant states. A series of 14 cases of barbiturate poisoning has been reported in which amphetamine was used to effect 13 recoveries, but a careful survey revealed that 9 of the patients would probably have recovered without such treatment. Handly and his co-workers favored the use of amphetamine in the treatment of morphine poisoning, but their series was very small. When the drug is used as an analeptic, there is some evidence that it is toxic and it also may cause slight analgesia. The use of amphetamine or other sympathomimetic amines alone as analeptics should be reserved until further data are forthcoming, but these drugs may profitably be combined with metrazol® or picrotoxin therapy.

Miscellaneous Drugs.—Studies of caffeine have shown it to be ineffective as an analeptic per se in moderate or deep narcosis. In normal subjects caffeine produces cortical stimulation, but when used in large doses in the treatment of narcosis it is inferior to other analeptics and is a depressant per se. It can be most effectively used as an adjunct to other analeptic agents. The use of camphor as a stimulant has almost ceased, and while alpha lobeline frequently exerts a decided, but brief, stimulant effect on respiration via the carotid body reflex, its effects are uncertain and usually followed by a period of depression due to a nicotinic action. Alpha lobeline is not to be recommended in view of the availability of other better analeptic drugs.

Succinate, Pyruvate and Fumarate.—The first attempt to use one of this group of substances in the treatment of depressant states was by Soskin and Taubenhaus, who found that sodium succinate shortened the duration of pentobarbital and amytal® anesthesia in rats and in 1 human being with barbiturate depression. Subsequent work on laboratory animals has failed to substantiate these observations in part or in whole. However, clinical reports have appeared claiming that succinate led to a decreased sleeping time in patients who had received thiopental sodium for anesthesia and facilitated the arousal of patients with barbiturate and morphine poisoning. In addition to succinate, pyruvate and fumarate have been investigated, but neither decreased the total depression time. There are apparently no reports of any of these substances having been used against severe depressant states.

At the present time the only justification for using these agents is that overdosage is not associated with convulsions. There is no other reason for one's substituting them for other standard analeptic agents at present. Further evaluation is needed, particularly as to what effect the diuresis produced by the agents has on their efficacy as analeptic drugs, before decision can be reached.

SOURCES OF ERROR IN CLINICAL REPORTS

Under the standard conditions of a laboratory investigation results obtained and conclusions drawn concerning the action of a given drug may differ considerably with the effect observed when the same drug is administered to patients. Animal weight, diet, hydration, season, mode of drug administration, rate of administration, interval between drug administration and onset of treatment and care of animals during treatment can all be standardized or controlled. The human patient presents an entirely different problem, which makes clinical investigation and the interpretation of its results more difficult. In the particular question at hand, species difference only partially explains the discrepancies of the laboratory and clinical reports, on the one hand, and the clinical reports from different institutions, on the other. The following discussion concerns factors that should be recorded during the treatment of any depressant state, since any of these factors may strongly influence the outcome of treatment. We would like to urge their inclusion in all clinical reports.

Renal Function.—Some of the depressant drugs are eliminated from the body primarily by excretion in the urine; this is particularly true of the longer-acting barbiturates. Failure to maintain an adequate urinary output may result in a retention of these barbiturates with a prolongation of narcosis. It is questionable whether an excessive output will increase the excretion of barbiturate over that which would be normally excreted, but in animals massive intravenous infusions started in less than 30 minutes after the barbiturates were administered shortened the sleeping time, presumably because of retention of a greater portion of the drug dissolved in body fluids, thus facilitating excretion. Urinary output and the type and amount of fluid intake should be recorded.

Visceral Pathologic Changes.—The existence of pathologic changes in body viscera, notably the kidney and liver, may lead to confusion in interpreting the results of analeptic therapy. Many of the depressants are detoxified in the liver; consequently a damaged liver will lead to a prolongation of a depression caused by any of this group of drugs. Renal damage will lead to a failure to excrete drugs normally eliminated through the urine. Summaries of case histories of depressant poisoning or analeptic therapy should always include notes of coexistent disease, even though at present there may seem to be no relationship between this and the depression.

Gastric Lavage.—Gastric lavage is an important early step in the treatment of depressant poisoning when the agent has been ingested. It, unfortunately, may lead to confusion as to the amount of depressant actually absorbed. Careful notes should be made concerning the interval between drug ingestion and gastric lavage and of any evidence suggesting that some of the drug was removed with the lavage.

Time Interval Between Drug Administration and Onset of Treatment.—There are observations suggesting that the shorter the interval between drug administration and the onset of treatment, the more likely is the treatment to be successful. Certainly if the time interval is sufficient to allow irreversible tissue changes to occur, chances for recovery are materially shortened. The larger the dose of depressant the more important this interval would become. Wherever possible the clinician reporting on such cases should include this information.

Synergistic Action of More Than One Depressant.—When more than one agent has been responsible for the depression, the results of treatment may be obscured. Alcohol and the barbiturates act synergistically; and analeptics are then less effective. In laboratory animals, subconvulsive doses of morphine and analeptics led to convulsions, suggesting that the treatment of morphine or barbiturate plus morphine poisoning with analeptics may be ineffective. However, it must be remembered that morphine is not convulsant in human beings. Sulfonamide drugs and barbiturates may act synergistically, suggesting that antibiotics may be safer to use to prevent secondary infection in barbiturate poisoning.

Overstimulation with the Analeptic.—When overstimulation occurs during analeptic treatment, the evaluation of the case becomes difficult or impossible. The secondary depression following a convulsion, whether or not a barbiturate was needed to control the convulsion, may lead to a death when otherwise a successful outcome might be achieved.

When Analeptics Should Be Used.—If the mechanism of action of an analeptic can be accepted as a physiologic antagonism to a depressant drug, it follows that the analeptic should only be used when a drug depression exists. Anoxia and asphyxia are not indications for the administration of analeptics; adequate pulmonary ventilation with 100 per cent oxygen may lead to the reinstitution of respiration under these conditions when analeptics has failed.

CONCLUSION

In the light of the available published data the apparent mechanism of action of analeptics is a physiologic antagonism to depressant drugs, but in view of the needed investigation on the problem this can be no more than a tentative conclusion. Picrotoxin and metrazol® (pentamethylenetetrazol) are the most valuable analeptics obtainable today, with picrotoxin being the most potent, judging from laboratory research. Picrotoxin is also more dangerous to use and should only be used in deep depressions and then by someone well versed in its actions. Before the true part played by these drugs in the treatment of depressions can be fully evaluated, more complete and detailed clinical summaries must be made and compiled. The use of analeptics in the treatment of depressions should be only a part of a carefully integrated schedule of treatment including oxygen therapy, pressor drugs, fluid and pulmonary ventilation if necessary, as well as more than one analeptic if indicated.

Council on Physical Medicine

REPORTS OF THE COUNCIL

The Council on Physical Medicine has authorized publication of the following reports. Howard A. Carter, *Secretary.*

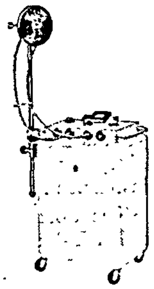
BIRTCHER CRYSTAL BANDMASTER SHORT WAVE DIATHERMY, MODEL 800 ACCEPTABLE

Manufacturer: The Birtcher Corporation, 5087 Huntington Drive, Los Angeles 32.

The Birtcher Crystal Bandmaster Short Wave Diathermy Model 800 has the U. S. Federal Communications Commission's Type Approval Certificate no. D-482 and operates on a frequency of 13.56 megacycles. The necessity for crystal control has been explained in The Journal, Sept. 6, 1947, pages 30-31. The apparatus is listed by the Underwriters' Laboratories, Inc.

This unit is shipped complete in one box. In the box is found the unit itself, a treatment arm with corner casting and treatment drum, a magnetic inductance cable, a line cord and a book of operating instructions.

The weight of the unit is given as 61 Kg. (135 pounds); the shipping weight is 98 Kg. (215 pounds). The dimensions are 91 by 55 by 43 cm. (36 by 21½ by 16 inches). The unit requires a 110 volt alternating current supply, and draws 7.5 amperes, making the power consumption 750 watts.



Birtcher Crystal Bandmaster S. W. Dia. Model 800

The cabinet and chassis are all steel, mounted on 7.6 cm. (3 inch) ball bearing, ball swivel casters. Large 30.5 cm. (12 inch) handles are built onto the steel cabinet to make the instrument readily mobile about the hospital or clinic.

The specimen submitted by the manufacturer was given a thorough clinical trial, and the Council obtained convincing evidence of satisfactory results with both the inductance cable and the circular disk applicator.

The Council on Physical Medicine voted to include the Birtcher Crystal Bandmaster Short Wave Diathermy Model 800 in its list of accepted devices.

PRECISION TABLE HEARING AID ACCEPTABLE

Manufacturer: Precision Electronics Company, 850 West Oakdale Avenue, Chicago 14.

The Precision Table Hearing Aid is designed for use in schoolrooms, homes, offices and other institutions where 115 volt 50 to 60 cycle alternating current is available. It is a ruggedly built hearing aid that can be set on a table or desk. Such an instrument can be much more economical than the battery-operated wearable types. The hearing aid amplifies sound from 100 to 15,000 cycles per second and peaks at the speech frequency range.

The Model 3AC21 submitted for examination was found to be a 3 tube so-called desk or table instrument designed to work from 110 volt alternating current lines. The case is constructed of light colored plywood and presents the general appearance of a midget radio. It is equipped with a crystal microphone, mounted in the front of the case. Output impedances are provided for use in either high or low impedance phones. The Precision Table Hearing Aid Model 3AC21 is marketed with dynamic or moving coil ear phones, crystal phones, high impedance magnetic phones or with the miniature hearing aid type of phone.

Combination on-off switch and volume control and tone control knobs are mounted on the front of the case. The tone control attenuates the low frequency response of the instrument.

A "Hi-Lo" switch on the back of the instrument regulates the maximum power output of the amplifier. The "Hi" position is intended for use with persons who have extreme hearing impairments.

This instrument is designed for instruction of children too young to wear individual hearing aids.

Dimensions.—225 by 156 by 125 mm. (8⅞ by 6⅛ by $4\frac{15}{16}$ inches).

Weight.—2.52 Kg. (5 pounds, 9 ounces).

Power Consumption.—21 watts.

Acoustic Gain for Speech.—The maximum gain for speech is limited by acoustic feedback. Consequently, the values obtained on hard-of-hearing persons reflect in part the tightness of the seal of the phones against the ears, the position of the subject in relation to the instrument and his distance away from it. Two adults who wear individual hearing aids, each with predominantly middle ear impairments of approximately 50 decibels, in a test perceived speech at a sound pressure level 40 to 44 decibels lower with this instrument than without it before feedback or squealing occurred while sitting about 4 feet from the aid.

Both preferred the quality of the dynamic and the crystal phones to the magnetic phones and the miniature hearing aid type crystal receiver.

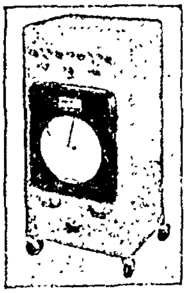
A phonograph input jack, which is provided in order that parents may take advantage of records for the speech training of hard of hearing children, is available for use with this instrument.

The Council on Physical Medicine voted to include the Precision Table Hearing Aid in its list of accepted devices.

COLEMAN ANOXIA PHOTOMETER, MODEL 17A, ACCEPTABLE

Manufacturer: Coleman Instrument Inc., 318 Madison Street, Maywood, Ill.

The Coleman Anoxia Photometer is a device designed to permit continuous observation of the degree of oxygenation of the circulating blood of the intact human subject. It utilizes the difference in color between oxidized and reduced blood, or, more specifically, the difference between oxidized and reduced blood as regards transparency to red light of wavelength between 600 to 700 millimicrons. Further details of theory and practice are given in a booklet of instructions.



Coleman Anoxia Photometer, Model 17A.

The apparatus consists essentially of two parts, a receptor or ear piece that is attached to the subject's ear and a cabinet that contains the indicating or recording instruments. The two parts are connected by a cable. The ear piece bears a light which shines through the more translucent parts of the external ear and is analyzed by the use of filters and photoelectric devices. The cabinet measures 94 by 36 by 46 cm. (37 by 15 by 18 inches). The apparatus weighs 57 Kg. (125 pounds); the domestic shipping weight is 73 Kg. (160 pounds), and the foreign is 95 Kg. (210 pounds). It requires a 115 volt alternating current supply, and draws 1 ampere or 115 watts. The instrument is available in two forms, the indicating and the recording. The indicating form utilizes a projection galvanometer that permits the observer to read the patient's relative oxygen saturation at any time; it is called Model 17-000. The recording form includes a device, separately housed, that provides a continuous record; it is Model 17-400. There is a third modification, Model 17-410, that includes all parts (with the exception of the ear pieces) in a single case. All models are provided with storage batteries to assure the constant voltage needed for their operation; there is also a battery charger that can be brought into action simply by closing a charging switch.

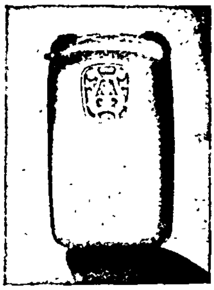
In practice, the ear piece is attached to the patient and the instrument is set at some assumed saturation level; thereafter the instrument will respond over extended periods to variations in saturation. If absolute instead of relative values are desired, the instrument must be calibrated on the basis of direct chemical determinations of the oxygen content of the blood by customary laboratory methods.

The Council on Physical Medicine voted to include the Coleman Anoxia Photometer, Model 17A, in its list of accepted devices.

SONOTONE HEARING AID, MODEL 900 ACCEPTABLE

Manufacturer: Sonotone Corporation, Elmsford, New York.

The Sonotone Hearing Aid, Model 900, is a so-called one piece three tube air or bone conduction instrument, the batteries of which are contained in the amplifier case. The front half of the case is constructed of metal with a rhodium finish and the back of the case is made of gray plastic. The lower half of the back of the case is hinged to give access to the battery compartments. Two different air conduction magnetic receivers, R-1 and R-2, and two different bone conduction oscillators, 01 and 02, are available for use with this instrument. The R-2 receiver has the wider frequency range, especially for the higher frequencies. The R-1 receiver is more efficient (more sensitive) for frequencies below about 1,800 cycles. The 02 bone conduction emphasizes the amplification of the higher frequencies more than the 01 receiver.



Sonotone Hearing Aid, Model 900.

Two wheel type controls are situated at the top of the case. One is a volume control; the other is a combination on-off switch and three position tone control—3 dot position for maximum wide range frequency response, 2 dot position for low frequency attenuation and 1 dot position for low frequency attenuation and about 10 decibel decrease in over-all amplification efficiency. A detachable wearing or attachment clip can be fastened either to the front or the back of the case. An extra battery cord is obtainable, which permits a large size external A battery to be used with this instrument for more economical operation if desired.

A series of tests gave the following data:

Dimensions.—111 by 67 by 25 mm. (4⅜ by 2⅝ by 1 in.).

Weight.—200 Gm., including batteries (7¼ ounces).

Battery Drain:

		Measured Voltage	Measured Current
A, Zinc and Carbon,	1.5 volts	1.4 volts	45 milliamperes
B, Zinc and Carbon,	22.5 volts	21.0 volts	0.56 milliampere

Acoustical Gain, Pure Tones:

Receiver	Tone Control Position	250	500	1000	2000	3000	4000 cycles
R1	3 dot	46.0	47.0	56.5	57.5	60.0	33 db.
R1	2 dot	34.5	41.5	54.5	57.0	60.0	33 db.
R1	1 dot	22.5	29.5	54.0	50.0	53.5	28 db.
R2	3 dot	36.5	32.5	38.5	51.5	63.5	41 db.

The gain of the bone conduction receiver was obtained in terms of gain for speech as described immediately below.

Gain for Speech.—The gain for air conduction with the RI receiver, 3 dot tone control position, was 50 decibels, with maximum gain setting of the volume control. This gain was obtained on 2 different hard of hearing persons having predominantly middle ear types of impairment, each of whom is an experienced user of hearing aids and has approximately 60 decibels unaided loss for speech with a speech audiometer. These persons perceived speech with 50 decibels less intensity from the loud speaker of a high quality sound amplification system (speech amplifier) in a sound-proof room with the hearing aid than without it.

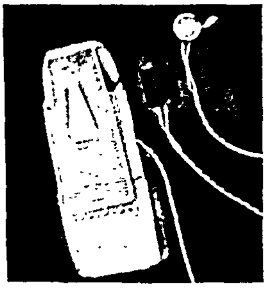
Equivalent gain for speech measurements with the 01 bone conduction oscillator, 3 dot tone control position, maximum volume setting, showed a gain for speech by bone conduction of 44 decibels. These measurements were obtained on 2 persons with approximately normal bone conduction acuity and uniform losses of 50 decibels for air conduction. Noise ascribable to clothing friction was reported to be low.

The Council on Physical Medicine voted to include the Sonotone Hearing Aid Model 900, in its list of accepted devices.

RADIOEAR PERMO-MAGNETIC HEARING AID (UNIPHONE ONE-PIECE MODEL) ACCEPTABLE

Manufacturer: E. A. Myers & Sons, Radioear Building, 306-308 Beverly Road, Mt. Lebanon, Pittsburgh 16.

The Radioear Permo-Magnetic Hearing Aid, Uniphone Model, is a three tube one piece hearing aid, designed to work in either an air conduction or a bone conduction receiver. The case is constructed of smooth, black or ivory plastic material, the lower front half of which opens to give access to the battery compartment. A magnetic type microphone and magnetic receivers are used with the instrument. Sound pressure variations reach the magnetic microphone diaphragm through recessed louvers on the side of the case adjacent to the microphone. This instrument is equipped with a "Phonemaster" coil adjacent to the microphone so that voice signals from the telephone may be picked up inductively and then amplified through the instrument's amplifier and miniature receiver. A wheel type combination on-off switch and volume control is located at the top of the case. A "Noisemaster" switch is on one side of the case and serves to attenuate both high and low frequencies in noisy environments if desired. A "Powerizer" switch, built into the amplifier chassis, makes it possible to regulate the maximum gain of the instrument over a 15 decibel range. The frequency response of the amplifier can be regulated by closing a hole in the microphone case and by adjusting the three position "Lo" and "Hi" tone-controls on the amplifier chassis. The "Powerizer" and tone control adjustments are accessible only after separating the front and back of the case.



Radioear Permo-Magnetic Uniphone Hearing Aid.

Dimensions: 168 by 64 by 25 mm. (6⅝ by 2½ by 1 inch).

Weight (including batteries, cord and air conduction receiver): 270 Gm. (9½ ounces).

Battery Drain:

		Measured Voltage	Measured Current
A, zinc and carbon,	1.5 volts	1.3 volts	40 milliamperes
B, zinc and carbon,	22½ volts	21 volts	0.19 milliampere

Acoustical Gain for Pure Tones:

Frequency	250	500	1,000	2,000	3,000	4,000 cycles
Maximum gain, air conduction	45	50	54	59	63	38 db.

Acoustical Gain for Speech: Two adults who wear hearing aids, each with predominantly middle ear impairments of approximately 50 decibels, perceived speech at a 44 decibel lower level by air conduction and 38 decibel lower level by bone conduction as measured by a speech audiometer. The "Phonemaster" reproduced speech at a level several (approx. 15) decibels higher than the average output level from telephone receivers.

The Council on Physical Medicine voted to include the Radioear Permo-Magnetic Hearing Aid, Uniphone One-Piece Model, in its list of accepted devices.

ALOETHERM CRYSTAL CONTROLLED SHORT WAVE DIATHERMY UNIT MODEL F-7300 ACCEPTABLE

Manufacturer: A. S. Aloe Company, Olive at Nineteenth Street, St. Louis 3.

The Aloetherm Crystal Controlled Short Wave Diathermy Unit Model F-7300 is an apparatus designed to deliver electromagnetic radiation with a frequency of 13.56 megacycles (22.12 meters), for administration of therapeutic heat to the tissues. The necessity for crystal control arises from the ruling of the Federal Communications Commission that it will be illegal to use, after July 1, 1952, any diathermy unit whose frequencies are not within assigned bands, in order to eliminate interference with commercial radio, amateur radio and television. The firm states that in general crystal control is the most effective and most widely used means of controlling the frequency range of diathermy apparatus, and that this method is less laborious and expensive than screening the treatment room.

The apparatus is contained within a case that can be moved about on casters. It is 107 cm. (42 inches) high, 66 cm. (26 inches) wide and 46 cm. (18 inches) deep. Without arms or cables it weighs 57 Kg. (125 pounds). When the drum is attached for use with the arm horizontally extended to its lowest vertical adjustment in the bracket and with the face of the drum parallel to the floor, the distance from the floor to the drum is 38 cm. (15 inches). When the arm is in full vertical extension with the drum at right angles to the floor the distance from floor to drum is 175 cm. (69 inches).

The unit operates on a 60 cycle alternating current of 110 to 120 volts. The chassis, bearing the transformers, condensers, tubes and crystal stage, can be lifted easily from the cabinet for inspection or servicing. With the apparatus there is furnished an electromagnetic treatment drum and electromagnetic inductance cable with spacers, a flexible arm and a line cord.

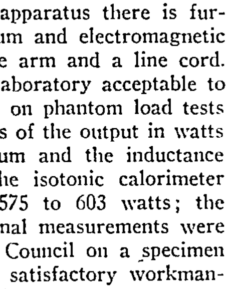
The firm submitted a report from a laboratory acceptable to the Council giving the results especially on phantom load tests made with Model F-7300. Measurements of the output in watts were made for both the inductance drum and the inductance cable, both the lamp load test and the isotonic calorimeter being used. The input ranged from 575 to 603 watts; the output, from 170 to 225 watts. Additional measurements were made in a laboratory acceptable to the Council on a specimen supplied by the firm, and the generally satisfactory workmanship, construction and performance of the apparatus were verified. It was noted that the apparatus is listed by the Underwriters' Laboratories.

The Council on Physical Medicine voted to include the Aloetherm Crystal Controlled Short Wave Diathermy Unit Model F-7300 in its list of accepted devices.

MEDIQUARTZ ULTRAVIOLET CABINET MODEL 420 ACCEPTABLE

Manufacturer: Medical Quartz Products Company, 5066 Santa Monica Boulevard, Los Angeles 27.

The Mediquartz Ultraviolet Cabinet Model 420 provides two sources of ultraviolet radiation. These are contained within a cabinet or box whose over-all dimensions are 41 by 23 by 12 cm. (16 by 9 by 4½ inches). It weighs 4.5 Kg. (10 pounds); the shipping weight is 6.8 Kg. (15 pounds). It operates on 110 volt alternating current and draws 69 watts. The cabinet is designed to be hung on a wall. Enameled with an ivory finish, it houses the controls in its lower portion; the upper portion has a glass door that gives access to the two ultraviolet generators. The cabinet contains the "Spot Irradiator" and the Orificial Applicator.



Mediquartz Ultraviolet Cabinet Model 420.

The Council on Physical Medicine voted to include the Mediquartz Ultraviolet Cabinet Model 420 in its list of accepted devices.

Please send in promptly notice of change of address, giving both old and new; always state whether the change is temporary or permanent. Such notice should mention all journals received from this office. Important information regarding contributions will be found on second advertising page following reading matter.

SATURDAY, MARCH 19, 1949

THE VOICE OF THE AMERICAN MEDICAL ASSOCIATION

"The objects of the Association are to promote the science and art of medicine and the betterment of public health."—Constitution of the American Medical Association, Article 2.

"The legislative body of the Association is the House of Delegates."—Constitution of the American Medical Association, Article 6.

"The House of Delegates is composed of delegates elected by the constituent associations and by the sections of the Scientific Assembly and of delegates from the Medical Departments of the United States Army, the United States Navy, the United States Public Health Service and Veterans Administration, appointed by the Surgeon General or Chief Medical Director, as the case may be, of the respective service."—Constitution of the American Medical Association, Article 6.

These quotations from the Constitution of the American Medical Association define clearly where responsibility lies for determining the policies of the Association. No committee, council, board, officer or employee of the Association is charged with establishing policies for the American Medical Association. The Association has not now and never has had an official spokesman.

In the Organization Section in this issue of The Journal appears an announcement by Dr. Elmer L. Henderson, Chairman of the Board of Trustees, concerning the present activities of the Board of Trustees in relation to extending medical care. In February the Board of Trustees announced the twelve point program, which is an expansion of other programs which the House of Delegates accepted and announced over a number of years. In making this announcement the Chairman of the Board of Trustees is not establishing any new policies. The announcement is made for information of the medical profession and the public concerning the activities of the Board of Trustees.

The employees of the American Medical Association now number about 800. Many councils, committees and bureaus are charged with specific duties by the Constitution and By-Laws. The President of the Association is elected annually as President Elect and succeeds to office one year following his election. His duties are specifically defined by the By-Laws, as are also the duties of each of the councils, committees and officers. All officials of the Association, including the President, the President Elect, the Secretary and the Chairman of the Board of Trustees, make public appearances and are interviewed. When they speak, they endeavor to interpret the policies of the House of Delegates. The employees of the Association, including the General Manager, the Editor, the secretaries of the various councils and committees and the directors of the bureaus, also make many public appearances; when they speak or when they are interviewed, they also present the policies adopted by the House of Delegates.

Recently the Association has established a division of public relations and has employed special public relations counsel in connection with a program of education of the American people regarding the present status of medical care and the proposals that have been made for extension of medical care. These agencies represent the American Medical Association. When they issue releases to the press or make public pronouncements, as they frequently do in delivering addresses, they also present the point of view of the House of Delegates.

The statements here made are intended to correct unwarranted misrepresentations as to the Association. The House of Delegates at the St. Louis session reaffirmed the point of view of the American Medical Association in its determined opposition to compulsory sickness insurance. The House of Delegates also recommended the widest possible extension of voluntary hospitalization and sickness insurance but did not consent to the formation of a national insurance company under the sponsorship of the American Medical Association. These are the two most prominent issues now discussed in editorial opinion throughout the United States. Until the House of Delegates acts to change a decision every council, bureau, officer and employee is bound by the prevailing actions of the House of Delegates.

CHOLINESTERASE INHIBITORS IN TREATMENT OF MYASTHENIA GRAVIS

The effectiveness of neostigmine in the treatment of myasthenia gravis is presumably based, at least in part, on the inhibiting power of this drug on cholinesterase. By controlling the enzyme, the specific function of which is to split acetylcholine, the transmission of the nerve impulse through the synapse at the myoneural junction in sufficient amount to create an adequate response in the skeletal muscle is, according to Nachmansohn,[1] thus made more certain. Similar action by other anticholinesterases, like physostigmine and strychnine, also prevents the rapid removal of the acetylcholine released during the passage of the nerve impulse. Further research has led to an investigation of some of the newer compounds known to inhibit cholinesterase, di-isopropyl-fluorophosphate (DFP), hexaethyl tetraphosphate (HETP), and tetra-ethyl pyrophosphate (TEPP).

---

[1] Nachmansohn, D.: The Role of Acetylcholine in Conduction, Bull. Johns Hopkins Hosp. 83: 463-496 (Dec.) 1948.

Di-isopropyl-fluorophosphate, when given intramuscularly, definitely lowers plasma and red blood cell cholinesterase activity for long periods. Comroe [2] and his associates have shown that di-isopropyl-fluorophosphate can also improve muscle strength in patients with myasthenia gravis. Closely parallel results were found by Gaddum and Wilson [3] and by Harvey, Lilienthal, Grob, Jones and Talbot.[4] The gain in muscular power, however, despite the fact that di-isopropyl-fluorophosphate may lower the plasma cholinesterase to zero, is not as great as that obtained with neostigmine, and the unpleasant central nervous and gastrointestinal symptoms evoked by di-isopropyl-fluorophosphate preclude its use in amounts sufficient to produce adequate therapeutic effects. The reason for the relative failure of di-isopropyl-fluorophosphate as a therapeutic agent has not been fully determined. Since it is a highly lipid-soluble compound, whereas neostigmine is water soluble, it may not act at the myoneural junction as readily and efficiently as does neostigmine. The better results obtained by neostigmine, moreover, may be due to the possibility that it has a direct action on skeletal muscle that is not shared by di-isopropyl-fluorophosphate.

A second anticholinesterase compound recently given clinical trial in myasthenia gravis is hexaethyl tetraphosphate (HETP). The effects are not dissimilar to those seen with di-isopropyl-fluorophosphate, according to Westerberg and Luros,[5] but the toxic symptoms, except those of central origin such as persistent nausea and insomnia, are more readily controlled by atropine. The drug exerts a prolonged effect similar to that noted after the use of di-isopropyl-fluorophosphate, and, when it is combined with neostigmine, the clinical results are moderately satisfactory. The limitation of hexaethyl tetraphosphate results largely from its instability in aqueous solution, a physical property not yet overcome. The results of the early studies are mildly encouraging, but the value of hexaethyl tetraphosphate as an acceptable therapeutic agent has yet to be established.

Somewhat more satisfactory are the clinical responses observed after the use of a third anticholinesterase preparation, tetra-ethyl pyrophosphate (TEPP). Although the side effects are similar to those seen after the use of di-isopropyl-fluorophosphate or hexaethyl tetraphosphate, the dose can be more easily regulated, being more stable, and it is effective when given by mouth. Burgen, Kelle and McAlpine [6] found the drug a completely effective substitute for neostigmine, and, although it is from a third to a half as potent, its action lasted about twice as long. Tetra-ethyl pyrophosphate is more cumulative than neostigmine, but less so than di-isopropyl-fluorophosphate. Because of its cumulative action, the response is more even than that of neostigmine. Harvey,[7] moreover, found that when tetra-ethyl pyrophosphate was given in amounts sufficient to increase the muscular strength above a basic level, but not to a maximum degree, there was a significant potentiation of the effect of all subsequent doses of neostigmine. Thus the combination of tetra-ethyl pyrophosphate and neostigmine, given orally, would appear to be of value in augmenting the present treatment of myasthenia gravis by neostigmine alone. Toxic symptoms, however, are frequent, some of them overcome by atropine. Until these are eliminated, di-isopropyl-fluorophosphate, hexaethyl tetraphosphate and tetra-ethyl pyrophosphate are still not superior to neostigmine in the treatment of myasthenia gravis.

DISCONTINUATION OF TEMPORARY APPROVALS OF RESIDENCIES

Elsewhere in this issue is an announcement by the Council on Medical Education and Hospitals that the Council will no longer grant temporary approval to residency training programs. Henceforth residencies will be considered for approval only after they have been inspected by representatives of the Council. By this action the Council has returned to its traditional policy of approving only those institutions which have actually been inspected by its representatives.

At the end of the war the tremendous expansion of residency training programs to accommodate returning veterans made it essential that a procedure be developed which would permit the prompt handling of the large number of applications for approval of newly created residencies. Accordingly, in February 1946, the Council in conjunction with the Advisory Board for Medical Specialties and the individual American Boards adopted a plan of granting temporary approval pending inspection to hospitals that submitted sufficient information about their training programs to enable the Council to make a tentative evaluation of their adequacy. Hospitals granted temporary approval were inspected as quickly as possible, and after inspection either they were given full approval or their approval was withdrawn. This program of granting temporary approvals made it possible in the space of three years to increase the number of approved residencies from just over 5,000 to more than 15,000. In general the program worked well, although instances occurred in which hospitals were granted approval when they would not have been granted approval had they actually been inspected.

[5] Westerberg, M. R., and Luros, J. T.: Clinical Use of Hexaethyl Tetraphosphate in Myasthenia Gravis, Univ. Hosp. Bull., Ann Arbor **14**: 15-17 (Feb.) 1948.

[6] Burgen, A. S. V.; Kelle, C. A., and McAlpine, D.: Tetra-Ethyl-pyrophosphate in Myasthenia Gravis, Lancet **1**: 519-521 (April 3) 1948.

[7] Harvey, A. McG.: Some Physiological Experiments of Nature in the Field of Neuromuscular Function: Tetra-Ethyl Pyrophosphate in the Treatment of Myasthenia Gravis, Potassium Deficiency, Potassium Intoxication, Proc. Inst. Med. Chicago **17**: 182-188 (Nov. 15) 1948.

The expansion of residency training has not halted, and it will now be possible to inspect all hospitals making application before granting approval. Approval based on the actual inspection of a hospital is essential for the maintenance of high standards of graduate training. Those hospitals holding temporary approval as of Jan. 1, 1949 will continue to hold such approval until they are inspected and decision is reached whether to grant them full approval or to withdraw approval.

The problem of appraising residency programs during the last three years has placed a burden on the Council and the American boards which cooperate with the Council. While delay in acting on applications has been unavoidable in many cases, the Council and the boards may take pride in the fact that during the period in question under their guidance the opportunities for residency training in the United States were more than trebled without any serious lowering of quality.

MORTALITY AND MORBIDITY STUDIES ON GROUP INSURANCE

A study of the frequencies of operations performed on employees and their dependents covered by group insurance contracts, and the charges made by the doctors for such operations, has just become available.[1] The claims studied were made in the periods from March 1946 to June 1947. The physicians' fees were collected from March 1947 to October 1947. Obstetrical benefits were omitted from this study.

The group of operations included tonsillectomy, appendectomy, benign tumor, hemorrhoidectomy, fracture, hysterectomy and herniotomy, which accounted for 58 per cent of the operations among employees and 69 per cent among the dependents. Tonsillectomy alone accounted for 60 per cent of the operations among children. The frequency for female employees was 23 per cent of all operations, and boys required 15 per cent more operations than girls.

When more than one operation was performed, the major operation or surgical procedure was coded as the first procedure; if it was not possible to make such a decision, the first procedure was determined by the largest reimbursement. The average reimbursement for multiple procedure claims was about twice that for single procedure claims. Female employees and wives of employees required more multiple operations than did the males; 24 per cent for female employees and 31 per cent for wives. Multiple procedure claims were reported in 17 per cent of the cases, with gynecology reaching a high of 51 per cent of this group and eye, ear, nose and throat operations at the other extreme of only 5 per cent. The most common combination of operations was hysterectomy and appendectomy, which represented 6.2 per cent of the total.

Most surgical treatment was performed in the hospital, but some was done out of the hospital; the reimbursement was lower for the latter type, usually less than 50 per cent of that for the inhospital surgical treatment. About 20 per cent of the employee operations and 13 per cent of the operations on dependents were performed out of the hospitals. Males had the largest amount of surgical treatment out of the hospitals.

The ratio of the reimbursement to the doctor's charge was about 54 per cent for all employees and 56 per cent for dependents. For the whole group it was 55 per cent. For every specific procedure the average charge for inhospital claims was greater than that for out of hospital claims; this reflects the tendency to perform the more serious operations in the hospital. In about 50 per cent of the cases the doctor's charge was not more than 92 per cent of the average charge per claim under the schedule of $150 maximum reimbursement; this is true for both inhospital and out of hospital claims. In 60 per cent of the cases the doctor's charge was not more than 106 per cent of the average charge.

Current Comment

EXCERPTA MEDICA

When the periodical *Excerpta Medica* was established in Holland, the authorities approached the American Medical Association with a view to a cooperative effort in the indexing and abstracting of medical periodicals. As a result of negotiations between Dr. M. W. Woerdeman, professor of anatomy and embryology in the University of Amsterdam, who is chairman of the board of editors, Dr. Morris Fishbein, Editor of The Journal of the American Medical Association, has been appointed one of the chief editors of *Excerpta Medica*. Studies are now in process to determine whether or not it will be feasible to indicate in the *Quarterly Cumulative Index Medicus* the articles that are abstracted in *Excerpta Medica* and also to utilize the services of the Dutch organization in the indexing of a greater number of periodicals than is now possible in the *Quarterly Cumulative Index Medicus*. UNESCO is also greatly interested in the development of a single international abstract of the important medical literature of the world. Conceivably from all these efforts great progress will be made in indexing and abstracting medical periodical literature.

ORGANIZATION SECTION

Official Notes

POLICY OF BOARD OF TRUSTEES FOR ACTION ON 12 POINT PROGRAM

In May 1948 a National Health Assembly was called by Federal Security Administrator Oscar Ewing in which all groups with an interest in medical care were represented. The assembly met in sixteen sections, each of which brought in a report constituting a plan for progress in health activities. The reports of these sections have not yet become available except for the inclusion of the condensed report of the section on medical care, by the Federal Security Administrator, in a report entitled "The Nation's Health: A Ten Year Program," published in September 1948.

When the full reports become available, the valuable material developed at the National Health Assembly may well serve as a basis of discussion and implementation of any program for the extension of medical care. When the National Health Assembly adjourned, most of those in attendance believed that the executive committee would carry on the studies and recommendations of that conference, but thus far only one meeting has been held. Otherwise, as far as can be determined, nothing has been done. The American Medical Association is ready to assume leadership in carrying out the recommendations of all of the sections which do not disagree with the fundamental policies established by the House of Delegates of the American Medical Association. Apparently the one point of issue remains the question of compulsory sickness insurance. The report of the section on medical care recommended the widest possible extension of voluntary hospitalization and sickness insurance. The House of Delegates at its meeting in St. Louis again reaffirmed its opposition to a system of compulsory sickness insurance.

The Board of Trustees of the American Medical Association is in constant touch and holds frequent conferences with various consumer groups and organizations. Proposals have been made for the American Medical Association to call another national health conference. It would be impractical to try to assemble another health conference until the report of the Assembly held in 1948 becomes generally available and until the reaction of the professions concerned and the public to those reports can be developed. The Board of Trustees wishes it clearly understood that it is prepared at the proper time not only to continue conferences already instituted but to call conferences with other consumer groups and to do whatever else is necessary to assure a better distribution of the high quality of medical care now existing in the United States.

Elmer L. Henderson, M.D.
Chairman, Board of Trustees,
American Medical Association.

MAYO CLINIC GROUP MEETS ASSESSMENT

Following is a letter sent by representatives of the Mayo Clinic and the Mayo Foundation to the secretary of the medical society with which they are affiliated:

Dr. H. M. Carryer, Secretary-Treasurer
Olmsted-Houston-Fillmore-Dodge County Medical Society
Mayo Clinic
Rochester, Minnesota

Dear Doctor Carryer:

In payment of the assessment of $25.00 requested of each of its members by the American Medical Association, we are pleased to transmit to the Olmsted-Houston-Fillmore-Dodge County Medical Society the attached check for $13,750.00. This sum is the payment of 210 members of the staff of the Mayo Clinic and 340 fellows of the Mayo Foundation, which is 97.7 per cent of the staff and 99.7 per cent of the fellowship personnel who are members of the local county medical society. The names of the individual physicians are attached. The figures given are exclusive of 20 staff members and 26 fellows who have not yet had the opportunity to contribute because of illness or absence from Rochester. There is every reason to believe that the response of this group will be equal to that cited above.

The members of the staff and the fellows of this institution are well aware of the efforts of the American Medical Association to devise methods for distributing medical care more widely by means of voluntary prepayment plans, and, almost unanimously, they desire to support these efforts.

It is to be hoped that such methods for extending medical care as might be devised by the American Medical Association will safe-guard or even improve the present high quality of medical service, and that the program will be such as to enlist the continued whole-hearted support of virtually all the physicians of the country. It is highly desirable that physicians present a united front in efforts to improve the distribution of medical care.

Arlie R. Barnes, M.D., Chairman
Board of Governors, Mayo Clinic
Victor Johnson, M.D., Director
Mayo Foundation for Medical
Education and Research

Washington Letter

(From a Special Correspondent)

March 14, 1949.

Hoover Commission Recommends New Agency

Establishment of a new federal agency—the United Medical Administration—to administer virtually all of the government's medical and hospital care, medical research and public health activities has been recommended by the Hoover Commission. As described in the official report just submitted to Congress, the United Medical Administration would absorb the United States Public Health Service, practically all continental hospitals of the armed forces and all medical-hospital functions of the Veterans Administration.

Effectuation of the Hoover Commission's proposals depends on (1) willingness of Congress to give President Truman the reorganization authority which he has requested and (2) the President's choice in the matter. Dr. Paul B. Magnuson, chief medical director of Veterans Administration, is on record in favor of the principle of consolidating federal medical services. Medical departments of Army and Navy are strongly opposed to relinquishing any of their hospitals. The Federal Security Agency, of which U. S. Public Health Service is a component, supports inclusion of federal medical services in the proposed Department of Welfare, rather than establishment of an independent United Medical Administration, responsible directly to the President, as recommended by the Hoover Commission.

As Secretary of Defense, James Forrestal abstained from participating in preparation of the report. Of the other eleven members, opinion was sharply divided over the major issue considered, whether or not a new agency should be set up. Scarcely a majority reached agreement on the United Medical Administration plan. Chairman Herbert Hoover and former Representative Carter Manasco dissented from the majority provision that the agency be served by a board that would be advisory only. Army, Navy, Air Force and Veterans Administration would be represented on the board. Representative Clarence J. Brown wrote a separate opinion protesting vigorously against absorption of military hospitals by a civilian branch of the federal government. Another member of the Commission, Senator John L. McClellan, concurred. Another minority opinion was submitted by Secretary of State Dean Acheson (vice chairman of the Hoover Commission), Senator George D. Aiken and James Rowe Jr., advocating integration of health services with education and security functions in a Department of Welfare.

The military would retain overseas hospitals, but all situated in this country would be surrendered, except certain station hospitals in outlying areas and one general hospital to be kept by each of the three armed services for research and teaching purposes. The plan further proposes that "professional personnel of the services might be assigned to the new administration for duty, research and training."

Indian hospitals and those administered by the Bureau of Prisons, Atomic Energy Commission, Tennessee Valley Authority and U. S. Soldiers Homes in Washington and Philadelphia would not be transferred. The proposed United Medical Administration, says the report, should be headed by "an outstanding administrator," but it is not required that he be a physician.

Ellender Defines His Position on Health Legislation

Senator Allen J. Ellender (Democrat, Louisiana) made it clear on March 5 that he is opposed to the Murray-Wagner-Dingell bill. The occasion was his weekly transcribed radio talk, broadcast by several Louisiana stations. He set forth his position on the health issue because several days earlier a news report had stated erroneously that he sided with Rep. John D. Dingell (Democrat, Michigan) in a televised debate in which the case against compulsory sickness insurance was argued by Senators H. Alexander Smith (Republican, New Jersey) and George W. Malone (Republican, Nevada). Actually, participants in the debate were Senator James Murray (Democrat, Montana) and Representative Dingell versus Senators Ellender and Malone.

"I want to again emphatically state," said Senator Ellender on March 5, "that I am opposed to socialized medicine in any form. I am opposed, specifically, to the President's compulsory health insurance plan now pending before Congress."

Representative Priest Heads Health Subcommittee

Representative J. Percy Priest (Democrat, Tennessee) has been appointed chairman of the newly formed subcommittee on public health, science and commerce of the House Committee on Interstate and Foreign Commerce. Formation of the subcommittee, which will handle national health, science foundation, local public health units and virtually all other medical and health legislation introduced in the House, was announced March 3—exactly two months after convening of the Eighty-First Congress. Other members are (Democrats) Representatives George G. Sadowski (Michigan), Thomas B. Stanley (Virginia), William T. Granahan (Pennsylvania), Andrew J. Biemiller (Wisconsin) and George H. Wilson (Oklahoma) and (Republicans) Representatives Joseph P. O'Hara (Minnesota), Wilson D. Gillette (Pennsylvania), Hugh D. Scott Jr. (Pennsylvania) and John B. Bennett (Michigan).

Under the chairmanship of Representative Priest, who also holds the important post of "whip" of the House Democratic membership, it will be up to the subcommittee to decide whether public hearings shall be held on the Murray-Wagner-Dingell bill, numerous special disease bills (multiple sclerosis, arthritis, epilepsy, cerebral palsy and others), proposed amendments of the Hill-Burton hospital survey and construction act, federal subsidization of local public health units and all enabling legislation involving the U. S. Public Health Service.

Hearings Open on Veterans Hospital Cutback

Scheduled to last for at least two weeks, hearings were opened March 10 by a special subcommittee of the Senate Labor and Public Welfare Committee on the proposed curtailment of the veterans hospital expansion program. Witnesses representing the American Legion and the Veterans of Foreign Wars, among the first to be heard, denounced President Truman's executive order of January 10 canceling plans for construction of twenty-four hospitals and reducing the size of fourteen others in order to effect a 16,000 bed cutback. Senator Claude Pepper (D., Fla.), chairman of the subcommittee, is opposed to the order, although he rarely takes exception to Truman policies. He has invited veterans' leaders, medical societies and public agencies in the nineteen affected states to send representatives here to testify on the cutback, with hearings scheduled to proceed until March 26.

Coming Medical Meetings

Alabama, Medical Association of the State of, Montgomery, April 19-21. Dr. Douglas L. Cannon, 519 Dexter Ave., Montgomery 4, Secretary.

American Association for Thoracic Surgery, New Orleans, March 29-31. Dr. Brian Blades, George Washington University Hospital, Washington, D. C., Secretary.

American Association of Anatomists, Philadelphia, April 13-15. Dr. Normand L. Hoerr, 2109 Adelbert Road, Cleveland 6, Secretary.

American Association of Genito-Urinary Surgeons, White Sulphur Springs, W. Va., Greenbrier Hotel, May 9-11. Dr. Norris J. Heckel, 122 S. Michigan Ave., Chicago 3, Secretary.

American Association of Industrial Physicians and Surgeons, Detroit, Book-Cadillac and Statler Hotels, April 5-9. Dr. Edward C. Holmblad, 28 E. Jackson Blvd., Chicago 4, Managing Director.

American Association of Pathologists and Bacteriologists, Boston, April 15-16. Dr. Howard T. Karsner, 2085 Adelbert Road, Cleveland, Secretary.

American Association on Mental Deficiency, New Orleans, Hotel Roosevelt, April 27-30. Dr. Neil A. Dayton, Box 51, Mansfield Depot, Conn., Secretary.

American Broncho-Esophagological Association, Chicago, Drake Hotel, April 18-19. Dr. Edwin N. Broyles, 1100 N. Charles St., Baltimore 1, Secretary.

American College of Allergists, Chicago, April 14-17. Dr. Fred W. Wittich, 423 LaSalle Medical Bldg., Minneapolis 2, Secretary.

American College of Physicians, New York, March 28-April 1. Dr. George Morris Piersol, 4200 Pine St., Philadelphia 4 Secretary General.

American Industrial Hygiene Association, Detroit, Book-Cadillac and Statler Hotels, April 5-7. Dr. Henry F. Smyth Jr., 4400 Fifth Ave., Pittsburgh 13, Executive Secretary.

American Laryngological, Rhinological and Otological Society, Chicago, Drake Hotel, April 18-20. Dr. C. Stewart Nash, 277 Alexander St., Rochester 7, New York, Secretary.

American Orthopsychiatric Association, Chicago, Stevens Hotel, April 4-6. Nina Ridenour, Ph.D., 25 W. 54th St., New York 19, Secretary

American Pediatric Society, Atlantic City, May 5-6. Dr. Henry G. Poncher, 1819 W. Polk St., Chicago 12, Secretary.

American Physiological Society, Detroit, April 19-22. Dr. Milton O. Lee, 2101 Constitution Ave., Washington 25, D. C., Executive Secretary.

American Society for Clinical Investigation, Atlantic City, May 2. Dr. Paul B. Beeson, Grady Hospital, Atlanta 3, Georgia, Secretary.

American Society for Experimental Pathology, Detroit, April 18-22. Dr. Frieda S. Robscheit-Robbins, 260 Crittenden Blvd., Rochester, N. Y., Secretary.

American Society for Pharmacology and Experimental Therapeutics, Detroit, April 18-22. Dr. Harvey B. Haag, Medical College of Virginia, Richmond 19, Secretary.

American Society for Research in Psychomatic Problems, Atlantic City, Chalfonte-Haddon Hall, April 30-May 1. Dr. Sydney G. Margolis, 714 Madison Ave., New York 24, Executive Secretary.

American Society of Biological Chemists, Detroit, April 17-22. Dr. Otto A. Bessey, 1853 W. Polk St., Chicago 12, Secretary.

American Surgical Association, St. Louis, April 20-22. Dr. Nathan Womack, University of Iowa, Iowa City, Secretary.

Arizona State Medical Association, Tucson, May 8-10. Dr. Frank J. Milloy, 15 E. Monroe St., Phoenix, Secretary.

Arkansas Medical Society, Little Rock, April 14-16. Dr. William R. Brooksher, 602 Garrison Ave., Fort Smith, Secretary.

Association of American Physicians, Atlantic City, May 3-4. Dr. Henry M. Thomas Jr., 1201 N. Calvert St., Baltimore 2, Secretary.

California Medical Association, Los Angeles, May 8-11. Dr. L. Henry Garland, 450 Sutter St., San Francisco 8, Secretary.

Connecticut State Medical Society, New Britain, State Teachers' College, May 3-5. Dr. Creighton Barker, 258 Church St., New Haven, Secretary.

Federation of American Societies for Experimental Biology, Detroit, April 18-22. Dr. Milton O. Lee, 2101 Constitution Ave., Washington 25, D. C., Secretary.

Florida [illegible] April 10-13. Dr. Robert B. McIver, 111 W [illegible] Secretary.

Georgia, [illegible] vannah, Hotel De Soto, May 10-13. Dr. E [illegible] ee St., N.E., Atlanta, Secretary.

Hawaii [illegible] on, Honolulu, May 5-8. Dr. Harry L. Ar [illegible] St., Honolulu, Secretary.

Iowa State Medical Society, Des Moines, April 18-21. Dr. Allan B. Phillips, 406 Sixth Ave., Des Moines 9, Secretary.

Kansas Medical Society, Topeka, May 9-12. Dr. D. D. Vermillion, 512 New England Bldg., Topeka, Secretary.

Louisiana State Medical Society, New Orleans, May 5-7. Dr. P. T. Talbot, 1430 Tulane Avenue, New Orleans 13, Secretary.

Maryland, Medical and Chirurgical Faculty of the State of, Baltimore, April 26-27. Dr. George H. Yeager, 1211 Cathedral St., Baltimore 1, Secretary.

Medical Library Association, Galveston, Texas, April 10-14. Miss Mildred R. Crowe, Medical College of Alabama Library, Birmingham 5, Ala., Secretary.

Michigan Postgraduate Clinical Institute, Detroit, Book-Cadillac Hotel, March 23-25. Dr. L. Fernald Foster, 2020 Olds Tower, Lansing 8, Mich., Secretary.

Minnesota State Medical Association, St. Paul, Municipal Auditorium, May 9-11. Dr. B. B. Souster, 496 Lowry Medical Arts Bldg., St. Paul 2, Secretary.

Mississippi State Medical Association, Biloxi, May 10-12. Dr. T. M. Dye, Box 295, Clarksdale, Secretary.

Missouri State Medical Association, Kansas City, March 27-30. Mr. T. R. O'Brien, 634 N. Grand Blvd., St. Louis 3, Secretary.

National Tuberculosis Association, Detroit, May 2-6. Dr. H. Stuart Willis, 1790 Broadway, New York 19, Secretary.

Nebraska State Medical Association, Omaha, Hotel Paxton, May 2-5. Dr. R. B. Adams, 416 Federal Securities Building, Lincoln 8, Nebraska, Secretary.

New Jersey, Medical Society of, Atlantic City, Hotel Ambassador, April 25-28. Dr. Earl L. Wood, 315 W. State St., Trenton 8, Secretary.

New Mexico Medical Society, Roswell, May 5-7. Dr. H. L. January, 221 W. Central Ave., Albuquerque, Secretary.

New York, Medical Society of the State of, Buffalo, Hotel Statler, May 2-6. Dr. Walter P. Anderton, 292 Madison Ave., New York 17, Secretary.

North Carolina, Medical Society of the State of, Pinehurst, The Carolina, May 9-11. Dr. Roscoe D. McMillan, P. O. Box 232, Red Springs, Secretary.

Ohio State Medical Association, Columbus, April 19-21. Mr. Charles S. Nelson, 19 E. State St., Columbus 15, Executive Secretary.
Rhode Island Medical Society, Providence, May 11-12. Dr. Morgan Cutts, 106 Francis St., Providence 3, Secretary.
Southern Branch, American Public Health Association, Dallas, Texas, Baker Hotel, April 14-16. Dr. George A. Denison, 600 S. Twentieth St., Birmingham, Ala., Secretary.
Southwest Allergy Forum, El Paso, Texas, Hotel Paso del Norte, April 4-5. Dr. O. E. Egbert, First National Bank Bldg., El Paso, Secretary.
Tennessee State Medical Association, Chattanooga, April 12-14. Dr. W. M. Hardy, 706 Church Street, Nashville 3, Secretary.
Texas, State Medical Association of, San Antonio, May 2-5. Dr. Harold Williams, 700 Guadalupe St., Austin, Secretary.
Western Association of Industrial Physicians and Surgeons, Los Angeles, Hotel Biltmore, May 7. Dr. Christopher Leggo, Crockett, Calif., Secretary.

Medical Legislation

STATE LEGISLATION

Connecticut

Bills Introduced.—H. 1063, to amend the workmen's compensation act, proposes to permit an injured employee a **free choice of physicians**. H. 1110 proposes that nothing in the general statutes shall be construed as prohibiting a physician licensed to practice medicine from prescribing any method or means for the **temporary prevention of pregnancy** in a married woman when in the opinion of such physician pregnancy would endanger the life or injure the health of such woman. H. 1413 and S. 901 propose the creation of a **system of health insurance**. H. 1577 proposes the appointment of a joint committee on public health and safety to "make an **intensive investigation on the subject of pain, sickness and death** and shall report to the governor not later than July 1, 1950, making recommendations for the elimination of pain, sickness and death." S. 657 proposes an appropriation to the state department of health to furnish services for children who have **cerebral palsy** or who are suffering from conditions which lead to cerebral palsy, such services to include the locating of the children, the provision of medical, surgical, corrective and allied services and care and the provision of facilities for hospitalization and after-care. S. 840 proposes to require physicians having knowledge that a wound has been caused as a result of the **discharge of a firearm** to report the same to the local prosecuting officer or state's attorney in the county in which he resides. S. 922 proposes to require all physicians and midwives to report **all cases of abortion** to the local prosecuting officer or the state's attorney in the county in which they reside. S. 965 proposes the establishment of an institution to be known as the **Connecticut Center for the Rehabilitation of Spastics** for the care, treatment, training and rehabilitation of spastics.

Idaho

Bill Introduced.—H. 290 proposes to authorize boards of county commissioners to levy a special tax to be used solely and exclusively for **preventive health services** by county boards of health.

Bill Enacted.—H. 34 has become chapter 23 of the Laws of 1949. It repeals and reenacts the existing medical practice act of the state with extensive amendments. Among other changes are the creation of an **independent state board of medical examiners**, provisions for the granting of temporary licenses and authorization to make use of the injunctive process in enforcing the provisions of the act.

Illinois

Bill Introduced.—S. 127 proposes the enactment of a **disability compensation act.**

Indiana

Bills Introduced.—S. 157, to amend the medical practice act, proposes to eliminate therefrom the provisions authorizing the use of the **injunctive process** to punish violators of the act. S. 259 proposes to make relevant in **actions involving illegitimacy** the results of blood tests of the complainant, her child and the defendant made to determine whether or not the defendant can be excluded as being the father of the child. The result of the test would be admissible in evidence only in cases where definite exclusion is established.

Iowa

Bill Introduced.—S. 339 proposes the enactment of a food and drug act providing, among other things, that any drug sold at retail and containing any quantity of **aminopyrine, barbituric acid, pituitary, thyroid** or their derivatives must be labeled in accordance with the provisions of the act unless it is sold on the written prescription of a doctor, dentist or veterinarian.

Kansas

Bills Introduced.—H. 200 proposes the enactment of a **board of nurse registration** and nursing education for the licensing of professional and practical nurses. Practical nursing would be defined by the proposal as meaning the performance for compensation, personal profit or gratuitously by members of religious communities, of such duties as are required in the physical care of a convalescent, a chronically ill or an aged or infirm patient, and in carrying out such medical orders as prescribed by a licensed physician, requiring a knowledge of simple nursing procedures but not requiring the professional knowledge and skills required for professional nursing. H. 307 proposes that regularly licensed schools for the purpose of **teaching chiropractic** shall have extended to them the same privileges as to the use of bodies for dissecting, demonstrating or teaching as those granted in this state to medical colleges.

Maine

Bill Introduced.—H. 1581, to amend the workmen's compensation act, proposes to permit injured employees to receive **chiropractic services.**

Maryland

Bills Introduced.—H. J. R. 11 proposes that the **Congress of the United States be memorialized not to enact legislation that has been proposed the effect of which will be to bring the practice of medicine in this country under federal direction and control.** H. 152, to amend the law relating to the **practice of chiropractic**, proposes, among other things, that a license to practice chiropractic shall not include the right to practice obstetrics. S. 211 proposes to amend the medical practice act so that the term "physician" shall be construed to **include chiropractic** as well as medical physicians.

Minnesota

Bills Introduced.—H. 419 proposes the enactment of a **disability benefits law.** H. 838, to amend the state narcotic act, proposes to include amidone, isoamidone, and keto-bemidome within the definition of "**narcotic drugs.**" H. 1091 proposes to make it unlawful for any female to submit to the act or operation of **artificial insemination**, or for any person to perform the act or operation of artificial insemination upon any female, or to assist, aid or abet any person in the performance of such act, or to donate, contribute or collect semen therefor, unless such woman is married and her husband has consented in writing under oath to such act or operation, and only the semen of the husband is used therefor. A child born in accordance with the provisions of this act would be considered the legitimate, natural child of both the husband and the wife for all purposes.

Nebraska

Bill Enacted.—L. B. 48 was approved Feb. 15, 1949. It authorizes counties to create the office of coroner's physician and provides that such physician shall make **postmortem examinations** of bodies and give testimony as to the same without witness fees in all inquisitions and state and county cases when called by the coroner, county or state.

Nevada

Bill Introduced.—A. 122, to amend the law relating to vital statistics, proposes to require physicians to report to the proper law enforcement officer any death which occurs during the **administration of any anesthetic** or during a surgical operation or any other medical procedure.

New Mexico

Bills Introduced.—H. 213 proposes to repeal a law enacted in the 1947 session which required all practitioners of the healing art to **designate the school of practice** which they intend to practice on all stationery, signs, advertisements, etc. S. 195 proposes to amend the **osteopathic practice act** by repealing the "as taught" definition of osteopathy and substituting therefor the following: "Persons who treat human ailments by that system of the healing arts which places the chief emphasis on the structural integrity of the body mechanism as being the most important factor for maintaining the organism in health."

North Carolina

Bill Introduced.—S. 96 proposes that a **physician or midwife** having charge of a birth of a **prematurely born infant** shall immediately give notification thereof to the local health department of the county in which the infant was born. S. 150 proposes to require every physician to notify the local health officer of the name of any person by whom such physician is consulted professionally and who is found to **have cancer of any type.**

Ohio

Bills Introduced.—H. 99 proposes the creation of a classification to be known as **public health sanitarian** which would be defined to mean a person trained in the field of sanitary science and sanitary technology who is qualified to carry out educational and inspectional duties and to enforce the law in the field of sanitation. H. 444 proposes to make it a **misdemeanor** for any person not licensed to practice a profession in the state **to advertise** in any manner whatever leading the public to believe that he is authorized to practice such profession or to list his name in any directory, newspaper, magazine, etc., suggesting that he is authorized to practice such profession or to use in connection with his name any word, title, symbol, letters or abbreviations suggesting that he is authorized to practice such profession or to offer any service, advice, counsel or assistance such as is customarily offered or rendered by persons licensed to practice such profession. S. 133 proposes the creation of a state **naturopathic board** of examiners and defines naturopathy as that philosophy and system of the healing art embracing prevention, diagnosis and the care of and treatment of human ills, diseases, traumas, deformities and functions by the use of the several properties of air, light, heat, cold, water, mechanics, electricity, manipulation and psychology, together with the use of such substances, largely nutritional, of plant, animal or mineral origin as are naturally found in and required by the body. Naturopaths, by virtue of this proposal, would not be permitted to practice major surgery or use x-ray, radium and radioactive substances for therapeutic purposes or to prescribe for internal use any substance required by law to be labeled poison. S. 151 proposes to amend the **privileged communications** statute so as to include communications between a physician and his patient in certain instances.

Wisconsin

Bill Introduced.—A. 314, to amend the workmen's compensation act, proposes to make the employer liable for reasonable expense incurred by an employee for fees of physicians and other experts appearing as witnesses in his behalf.

GOVERNMENT SERVICES

ARMY

REORGANIZATION OF ARMY HOSPITALS TO CONSERVE MEDICAL PERSONNEL

The Surgeon General of the Army announced March 1 the proposed streamlining of wartime military hospitals in overseas theaters to effect greater economy in the use of personnel in scarce professional categories. The proposed organization is the result of a study of the experiences of the Army Medical Department in overseas theaters during combat. The main wartime obstacle was the lack of flexibility in the use of professional personnel inherent in the older and more rigid Table of Organizations, under which equipment and personnel were welded together as a unit. This concept required larger numbers of professional personnel and was responsible for much enforced idleness during the war. The proposed plan reduces the number and type of medical organizations and authorizes a split between equipment and administrative, on the one hand, and professional personnel on the other.

Under the new plan, which has the approval in principle of the General Staff, the "professional complement," as it will be called, will not join the unit until the last practical moment. In this way, the personnel in scarce categories will be available for use at other installations, or may even remain longer in the civilian community, until the time when they are actually needed with their parent unit.

"The idleness of valuable personnel had serious effects," the Surgeon General stated. "These professional men and women were not being used economically. More physicians, dentists, nurses and others were called into the service than necessary, creating a shortage in the civilian economy and adversely affecting morale in civilian as well as military medical circles."

The final details will be field tested in the near future. It is expected there will be more units consisting of equipment and administrative personnel than there will be professional complements. It is planned that the professional complements, once their duties in a hospital have been completed and the patients evacuated, will move as a team to another hospital unit which has been made ready in a more forward area of the combat zone. Professional complements will be further augmented by specialist teams as required. This will likewise contribute to greater utilization of specialists.

OFFICERS TO PURSUE ADVANCED CIVILIAN COURSES

The following medical officers have been accepted for advanced courses in the civilian schools and hospitals indicated:

Col. Wendell A. Weller, University of California, San Francisco, ear, nose and throat pathology.

Lieut. Col. T. Donald McCarthy, University of Kansas Medical Center, Kansas City, *radiology physics.*

Major Herbert P. Sube, University of California, San Francisco, ear, nose and throat pathology.

Capt. Ralph N. Kraus, University of California, San Francisco, ear, nose and throat pathology.

Capt. Marion E. McDowell, University of Rochester, School of Medicine and Strong Memorial Hospital, Rochester, N. Y., residency training in internal medicine.

Capt. Frederick F. Krauskopf, Jackson Memorial Hospital, Miami, Fla., assistant residency in surgery.

Capt. Richard A. Hayden, St. Mary's Hospital, Brooklyn, residency in obstetrics and gynecology.

Capt. Russel R. Jauernig, Bellevue Hospital, New York, residency in radiology.

Capt. Walter G. Olin Jr., Patterson General Hospital, Patterson, N. J., residency in pathology.

First Lieut. Bryan Williams Jr., Massachusetts Memorial Hospital, Boston, intern training.

First Lieut. Frederick Charles Biehusen, Grace-New Haven Community Hospital, New Haven, Conn., residency in pediatrics.

First Lieut. Arthur W. Adams, Ellis Hospital, Schenectady, N. Y., internship in surgery.

First Lieut. Norman Goldstein, Lincoln Hospital, New York, residency in pediatrics.

First Lieut. Robert Franklin Hufner, Meadowbrook Hospital, Hempstead, New York, *residency in pathology.*

First Lieut. Lester D. Johnson Jr., Georgetown University Hospital, Washington, D. C., residency in obstetrics and gynecology.

First Lieut. Ralph G. Thomas, Indianapolis General Hospital, Indianapolis, residency in general surgery.

First Lieut. John S. Kelly, Cook County Hospital, Chicago, residency in general surgery.

First Lieut. John A. Norman, Children's Hospital, Denver, residency in pediatrics.

First Lieut. John N. Palmer, Provident Hospital, Chicago, residency in surgery.

First Lieut. Harry Banoff, Los Angeles County General Hospital, residency in ophthalmology.

First Lieut. Charles B. Crow Jr., Boston City Hospital, Boston, assistant resident in medicine.

First Lieut. George R. Barnes Jr., Grace-New Haven Community Hospital, New Haven, Conn., residency in pediatrics.

First Lieut. Ben D. Hall, John Gaston Hospital, Memphis, Tenn., residency in medicine.

First Lieut. Saul B. Appel, New York University–Bellevue Medical Center, New York, residency training in medicine.

First Lieut. Willis H. Thornburg, New York Post-Graduate Medical School and Hospital, New York, residency in surgery.

First Lieut. Robert A. Simenson, Worcester State Hospital, Worcester, Mass., *residency in psychiatry.*

VACANCIES IN MEDICAL SERVICE CORPS

A number of vacancies in the grades of second and first lieutenant still exist in the Army Medical Service Corps in bacteriology, biochemistry, parasitology, serology, entomology, nutrition, toxicology, industrial hygiene, industrial hygiene engineering, optometry, psychiatric social work, clinical psychology and sanitary engineering, under the provisions of Department of Army Circular 210 dated July 14, 1948. Although most of the provisions of Circular 210 were suspended as of Feb. 15, 1949, pending completion by the Department of the Army of a study of remaining requirements, applications for reserve commissions in most grades are still being accepted by the Medical, Dental, Veterinary, Nurse and Women's Medical Specialist Corps as well as by the Medical Service Corps for appointment in the grades of second and first lieutenant.

THE DARNALL EXHIBIT

The Army Medical Library, Washington, D. C., has been conducting a series of exhibits entitled "Famous Men of Army Medicine." The subject of the seventh exhibit in this series is the late Carl Rogers Darnall, whose investigations and inventions made modern water purification possible. The method which, then Major, Darnall of the U. S. Army Medical Department originated in 1910 was the introduction into water supplies of chlorine gas, a method which has since been adopted throughout the world. Safe drinking water today is so universally obtainable that few persons recognize the great significance of modern water purification in relation to public health. The pictorial part of the exhibit concerns the application of the Darnall method both in the Pacific and European Theaters of Operation in World War II. Much of the Darnall experimentation to develop this method was carried on during his period of service on the faculty of the Army Medical School in Washington, D. C. Major Darnall later attained the rank of brigadier general and was awarded the Distinguished Service Medal for outstanding service in administering the activities pertaining to medical supply during World War I.

MONTHLY MEDICAL MEETING

At the Surgeon General's regular monthly meeting of medical officers at Walter Reed Hospital, February 17, Dr. Frank Meleney of the Department of Surgery, Columbia University, New York, spoke on "Bacitracin: Indications and Limitations of Its Systemic Administration in the Treatment of Infections." After the meeting refreshments were served in the Officers' Club.

PERSONNEL

Lieut. William J. Brown Jr., M.C., formerly at Ft. Lawton, Washington, D. C., has been assigned to the staff of the Army Institute of Pathology, Washington, D. C., as tissue pathologist.

NAVY

EXAMINATIONS FOR APPOINTMENT IN MEDICAL CORPS

Examinations for the selection of candidates for appointment to the grade of lieutenant (junior grade) in the Medical Corps of the Navy will be conducted at all Naval hospitals in the continental United States during the period April 4-8, 1949.

Graduates of approved medical schools in the United States or Canada who have completed intern training in accredited hospitals or who will complete such training within four months of the date of the examination, and who are physically and otherwise qualified, may be examined for appointment. Candidates must be less than 32 years of age at the time of appointment and will be required to appear before boards of medical examiners and supervisory Naval examining boards at the Naval hospital nearest their residence to demonstrate their physical and professional qualifications. After approval by the President of the United States and confirmation by the Senate, selected candidates will be issued appointment and orders assigning them to duty in a Naval medical facility.

As a result of the authorized additional compensation of $100 a month for medical officers, a lieutenant (junior grade) in the Navy Medical Corps receives pay and allowances totaling $5,011.00 a year if married and $4,575.00 if without dependents.

Information concerning procedure of application may be obtained from the nearest Naval Officer Procurement Office or from the Bureau of Medicine and Surgery, Navy Department, Washington 25, D. C. (Attn: Code-3424).

FIRST ACTIVE DUTY

The following lieutenants (jg) in the Medical Corps Reserve have been nominated for courses of instruction under the Navy's Graduate Medical Training Program: Wayne C. Brady of Statesville, N. C., to a residency in orthopedic surgery at Columbia Hospital of Richmond County, Columbia, S. C.; Ward Cooper Jr. of Palo Alto, Calif., to instruction in ophthalmology at the Naval Hospital, Oakland, Calif.; Raymond J. Leffler of Iowa City to a residency in pathology at Robert Packer Hospital, Sayre, Pa.; Wolfram G. Locher of Chardon, Ohio, to a residency in anesthesiology at Reading Hospital, Reading, Pa., and Robert G. Trout of Columbus, Ohio, to a basic course in surgery at the University of Pennsylvania Graduate School of Medicine, Philadelphia.

POSTGRADUATE INSTRUCTION

The following Regular Navy medical officers have been nominated for postgraduate courses of instruction as indicated:

Name	Residence	Course
Dement, Donald E., Capt.	Grosse Ile., Mich.	Training in the National Laboratories, Oak Ridge, Tenn.
Hoot, Paul M., Capt.	Ponca City, Okla.	Training in the National Laboratories, Oak Ridge, Tenn.
Kwiatkowski, Peter S., Lieut. Comdr.	Binghampton, N.Y.	Training in the National Laboratories, Oak Ridge, Tenn.
Yocum, Thomas D., Lieut.	Versailles, Ky.	Children's orthopedics at the Miller Orthopedic Clinic, Charlotte, N. C.
Fahrner, Robert J., Lieut. (jg)	Joliet, Ill.	Residency in obstetrics and gynecology at the Naval Hospital, Long Beach, Calif.
Gardipee, Charles R., Jr., Lieut. (jg)	San Francisco	Residency in general practice at the Naval Hospital, Long Beach, Calif.
Lewis, Garner L., Lieut. (jg)	Kingston, N. Y.	Training in the National Laboratories, Oak Ridge, Tenn.
Park, William F., Lieut. (jg)	Baltimore	Residency in otolaryngology at the Naval Hospital, Bethesda, Md.

PERSONAL

Lieut. (jg) Robert A. Loeffler of Medford, Ore., has been transferred from an active reserve status to the Medical Corps of the Regular Navy and is on duty at the Naval Hospital, San Diego, Calif., for a course in general surgery.

PUBLIC HEALTH SERVICE

STUDY OF PUBLIC HEALTH SERVICE GRANTS AND FELLOWSHIP PROGRAMS

On the recommendation of the National Advisory Health Council, a special committee has been appointed by the Surgeon General of the Public Health Service to study the Public Health Service research and educational grants and fellowships, the cost of medical education and the effect of these grants on medical school finances and on medical education. The purpose of this study is to evaluate existing grant and fellowship programs and policies and to provide a basis for advice on the financial needs of medical education. The members of this committee are:

Dr. Lowell J. Reed, Chairman
Dr. George Baehr
Dr. Robin C. Buerki
Dr. Edward A. Doisy
Dr. E. G. Gustavson
Dr. Algo Henderson
Dr. E. E. Irons
Dr. Carlyle Jacobsen
Dr. Hugh Morgan
Dr. B. O. Raulston
Dr. James S. Simmons
Dr. Herman B. Wells

The special committee has consulted with the Committee on the Survey of Medical Education, sponsored by the Council on Medical Education and Hospitals of the American Medical Association and the Association of American Medical Colleges. While the two committees will carry out their studies independently, every effort is being made to coordinate their activities with the view of avoiding unnecessary duplication of work and reducing the demands on the officers and faculties of the medical schools.

The study by the Surgeon General's committee will be conducted through a series of regional meetings of the deans and finance officers of the medical schools and through subsequent interviews by a representative of the committee. The first regional meeting will be held in Atlanta on March 21. Meetings in other regions are being scheduled for April.

NURSES NEEDED FOR GOVERNMENT POSITIONS

The U. S. Civil Service Commission announces an examination for Public Health Nurse for vacancies in Washington, D. C., and vicinities and others in territories and possessions of the United States. No written test is required. Applicants must have completed a three year nursing course or a two year nursing course plus appropriate experience or education, and they must have had a minimum of one year's experience in public health nursing in a generalized community public health program. All applicants must be registered as professional nurses in some state or territory at the time of appointment. These positions pay from $3,727 to $4,479 a year. Details and application forms may be obtained from the U. S. Civil Service Commission, Washington 25, D. C., or from most first and second class post offices. Applications must be on file with the Commission not later than March 29, 1949.

EUROPEAN INFLUENZA CENTERS

The Influenza Information Center, National Institutes of Health, has received a list of European influenza centers from Dr. C. H. Andrewes, World Influenza Centre, London. The centers were established as part of the World Health Organization Study Program. Following is the list:

Laboratoire Central d'Hygiene, Brussels, Belgium.
State Serum Institute, 80 Amager Boulevard, Copenhagen, Denmark.
Virus Laboratory, St. Vincent's Green, Dublin, Ireland.
Institut Pasteur, Rue du Dr. Emile-Roux, Paris XV, France.
State Laboratory, Ministry of Hygiene, Athens, Greece.
Institute of Hygiene, Budapest, Hungary.
University Institute for Experimental Pathology, Keldur, Iceland.
Instituto Sieroterapico Italiano, Naples, Italy.
University Laboratory, Oslo, Norway.
Swedish State Bacteriological Laboratory, Box 764, Stockholm 1, Sweden.
Institut [illegible] 'efik Saydam," Ankara, Turkey.
Federal [illegible] Belgrade, Jugoslavia.

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

CALIFORNIA

Multimillion Dollar Medical Building Program.—The regents of the University of California have approved the multimillion dollar building program to erect on the Los Angeles campus a complete medical research center. Scheduled for immediate construction is the $15,500,000 medical school and teaching hospital which will form the nucleus of the project on 35 acres at the south end of the Los Angeles campus and 34 acres nearby, recently deeded to the university by the United States government. The central structure will combine a medical school and a 500 bed teaching hospital, as well as provision for 114 additional student health service beds. The radiology department and surgical operating rooms will be built underground, representing an innovation in the construction of a modern hospital. Also unprecedented is the interior planning whereby classrooms and laboratories devoted to a particular medical subject will occupy the opposite wing on the same story as the corresponding ward in the training hospital, thus permitting students to examine appropriate patients without leaving the floor. Architecturally, the hospital-school will be flexible, with a modular system in 5 foot units providing infinite variety of floor plan arrangements and a peripheral piping system that makes possible the immediate conversion of any room into a fully equipped laboratory with the addition merely of fixtures. The exterior of the building has been designed to allow expansion in nine horizontal directions, and vertically to the Los Angeles height limit. Other buildings to be erected include a student health service, outpatients' clinic, interns' and nurses' quarters and library. Plans call for the addition of an atomic energy medical research unit, buildings devoted to mental hygiene and aviation medicine, cancer and cardiovascular research units. According to Dr. Stafford Warren, dean of the University's Los Angeles Medical School, the new center will represent "a full scale effort to coordinate the basic sciences and clinical sciences within the walls of a single university." Various academic departments of the university will be closely allied to related departments in the new center, with undergraduates in other departments sharing libraries, laboratories and even some classrooms with medical students.

COLORADO

Reporting of Animal Diseases.—The state department of public health has instituted a program of reporting animal diseases which are transmissible to human beings. Each veterinarian furnishes reports on forms designed for this purpose. Additional information may be obtained from Martin D. Baum, D.V.M., director, Veterinary Public Health Services, State Office Building, Denver 2.

Course in Problems of Newborn Infants.—A graduate course on The Problems of Newborn Infants, to be sponsored by the University of Colorado School of Medicine, Denver, and the Colorado State Division of Public Health, will be given at the University of Colorado Medical Center, Denver, April 7-9. Lectures, panel discussions and demonstrations will be given on obstetric aspects of prematurity, resuscitation, nutrition, isoimmunization, psychologic problems in prematurely born infants, community planning, infections and interpretation of laboratory findings in the newborn. The guest lecturer is Dr. Herbert C. Miller Jr., professor of pediatrics, University of Kansas School of Medicine, Lawrence-Kansas City. The course is open to graduates of medical schools approved by the American Medical Association. The registration fee is $5 and the tuition is $10. Interns and residents are invited to attend without charge. Inquiries should be directed to John Lichty, M.D., director of the course.

CONNECTICUT

State Cancer Conference.—The second annual State Cancer Conference of the Connecticut State Medical Society and the Connecticut Cancer Society will be held March 23 at the Hartford Club, Hartford. Visiting physician speakers include:

Oliver Cope, Boston, Radioactive Isotopes in Diagnosis and Treatment of Cancer.
Richard H. Sweet, Boston, Cancer of the Esophagus and Stomach.
William Dameshek, Boston, Leukemias.

Hospital for Alcoholism.—A publicly supported hospital devoted solely to the study, treatment and rehabilitation of alcoholic addicts of the state is to be erected in Hartford within the next year. Funds totaling $551,943 have been made available by the state for the two story structure which will have accommodations for 50 bed patients and an outpatient department to treat about 400 ambulatory patients annually. It will be directed and operated by the Connecticut Commission on Alcoholism. Treatment will be entirely professional in character with full medical, psychiatric, nursing and social work service available. It will serve as a pilot and demonstration center through which various therapeutic technics can be evaluated. It will undertake the study and treatment of the voluntary type of alcoholic addict who seeks assistance and the patient with a long history of court appearances for chronic alcoholism.

DISTRICT OF COLUMBIA

Dr. James G. Cumming Retires.—Dr. James Gordon Cumming will retire as director, Bureau of Preventable Diseases, of the District of Columbia Health Department after twenty-four years of service. After graduation from the University of Michigan in 1903, Dr. Cumming taught at the medical school until 1914 and was director of the university's Pasteur Institute. From 1914 to 1918 he served as director of the Bureau of Communicable Diseases, California State Department of Health, and was lecturer in preventive medicine at the University of California Medical School, Berkeley-San Francisco. For World War I service in connection with studies of epidemic influenza and pneumonia Dr. Cumming was awarded the Distinguished Service Medal. He was assigned to the Office of the Surgeon General of the Army in Washington to assist in the preparation of the medical and surgical history of World War I. Dr. Cumming plans to retire to his farm in Indian Head, Md.

GEORGIA

School of Medical Illustration.—The first school of medical illustration in Southeastern United States has opened at the University of Georgia School of Medicine, Augusta. Work is available for medical students and for medical art students who wish to take advanced work in a particular branch and to scientific illustrators. A regular four year course for beginners is also available. A limited number of applicants are selected each year. Applications for admission may be addressed to the Registrar, University of Georgia School of Medicine, Augusta.

ILLINOIS

Appointments to Crippled Children's Committee.—Nine new members, each to serve two years, have been appointed to the Professional Advisory Committee of the Division of Services for Crippled Children by the University of Illinois Board of Trustees. Five appointees from Chicago are: Mr. Ray E. Brown, superintendent of the University of Chicago Clinics; Drs. Francis J. Gerty and H. Worley Kendell, University of Illinois College of Medicine; Dr. Meyer A. Perlstein, and Miss Jane Bull, executive director of the Illinois Commission for Handicapped Children. Others are Mr. Isaac Jolles, State Department of Public Instruction, Springfield; Drs. Stuart Broadwell Jr., Springfield otologist; Frederick H. Maurer, Peoria pediatrician, and Harold Westlake, Ph.D., Northwestern University.

Chicago

Davis Lecture on Medical History.—Paul M. Angle, LL.D,. director of the Chicago Historical Society, will give the sixth annual D. J. Davis Lecture on Medical History March 30 in Room 221 of the University of Illinois College of Medicine. His subject will be "The Hardy Pioneer: How He Lived in the Early Middle West." This lecture series was established by friends and associates of Dr. Davis on his retirement as dean of the College of Medicine in 1943.

Appoint Assistant Dean.—Dr. Milan V. Novak, a member of the faculty of the College of Medicine since 1940, has been appointed assistant dean of the Graduate College for the University of Illinois' Chicago Professional Colleges. He will continue to serve also as head of the department of bacteriology. He will be in charge of administrative duties for the Graduate College on the campus of the Chicago Professional Colleges. The new position has been created by the university because of the increase in enrolment of graduate students, together with the need for expediting routine connected with this work. The number of students enrolled in graduate work on the Chicago campus has tripled since the close of the war.

Cleft Palate Training Center.—Clinical training in the care of children with cleft palate has been established at the University of Illinois. A special clinic for research, diagnosis and follow-up of children with cleft lips and palates is being set up in the university's Dentistry-Medicine-Pharmacy building. Primary financial support will come from the Children's Bureau of the Federal Security Agency, which has granted $175,000 for a period of four to five years. Herbert K. Baker, Ph.D., professor of audiology and director of speech and hearing rehabilitation in the college of medicine, has been appointed director. The new program will make possible long term follow-up and research in the value of various aspects of the care of cleft palate children.

Welfare Council Asks for Additional Funds.—The Health Division of the Welfare Council of Metropolitan Chicago has appealed to the governor and the legislature to appropriate additional state funds for adequate health protection for the people of Illinois. It was emphasized that this can only be attained through local health departments. The state health department is not equipped to do the thorough job necessary, it was said. The Illinois Department of Public Health has available annually about $4,700,000, of which about $2,000,000 is from federal sources and the balance from state funds. The Chicago Board of Health receives no state funds, according to the council, but has been allotted $543,160 in federal funds through the state department to be used for mental hygiene and tuberculosis and venereal disease control. The Cook County Health Department is receiving $118,657 from the state, and the Evanston Health Department is receiving $34,236. Among deficiencies in health protection for the city, the council listed virtually no health services for nearly 750,000 school children in the city; no health supervision for preschool age children in at least 80 per cent of the city; the need of 100 additional sanitary inspectors; the urgent need of 250 public health nurses, and virtually no public health programs to conserve health through health education, mental hygiene and health services for the aged. California and New York, according to the council, provide grants-in-aid for local health work on a much more liberal basis than Illinois. California distributes $3,000,000 annually and New York provides at least 50 per cent of the funds for local public health work, and in poorer communities up to 75 per cent.

IOWA

Iowa Heart Association.—A group of Iowa physicians recently organized the Iowa Heart Association as an affiliate of the American Heart Association. Dr. Herbert W. Rathe, Waverly, was named president and Dr. Lewis E. January, secretary. Both are faculty members of the State University of Iowa College of Medicine, Iowa City.

State Medical Meeting.—The Iowa State Medical Society will hold its annual session at Hotel Fort Des Moines in Des Moines April 18-21, under the presidency of Dr. William E. Ash, Council Bluffs. Guest speakers at the general sessions include:

Harry H. Gordon, Denver, Problems in the Diagnosis and Treatment of Rheumatic Fever.
Richard B. Cattell, Boston, Inflammatory Lesions of the Small and Large Bowel.
Arthur L. Conrad, J.D., Chicago, Social, Moral and Economic Implications of Political Medicine.
Lawrence R. Boies, Minneapolis, Headache and Neuralgia of Nasal Origin.
Walter H. Nadler, Chicago, Sarcoidosis.
Louis A. Buie, Rochester, Minn., Ulcerative Colitis.
Walter P. Blount, Milwaukee, Fractures in Children Are Different.
Forrester Raine, Milwaukee, Diagnostic Difficulties in Carcinoma of the Lungs.
William F. Mengert, Dallas, Tex., Pelvic Pain in Women.
William A. Boice, Chicago, Indications for Cesarean Section.
Abe B. Baker, Minneapolis, Treatment of Epilepsy by the General Practitioner.
Austin Smith, Secretary, Council on Pharmacy and Chemistry, American Medical Association, Chicago, Food and Drug Act.
Arthur M. Olsen, Rochester, Minn., Differential Diagnosis of the More Common Pulmonary Conditions.

Section meetings on surgery, medicine, pediatrics, obstetrics and eye, ear, nose and throat will be held in the afternoons.

KANSAS

Course in Ophthalmology and Otolaryngology.—The University of Kansas in cooperation with the Kansas Society of Ophthalmology and Otolaryngology, the Kansas Medical Society and the state board of health will present a graduate course in ophthalmology and otolaryngology at the university medical center in Kansas City April 11-15. It is open to any doctor of medicine in the state and adjacent states. Among the instructors will be Drs. Stuart C. Cullen, Iowa City; Frank S. Forman Jr., Kansas City, Mo.; Arthur C. Jones, Boise, Idaho; Albert D. Ruedemann, Detroit, and Benjamin H. Shuster, Philadelphia. A fee of $30 is charged for the full course, $20 for the first three days in otolaryngology only, or for the last two $15. Complimentary enrolment is granted to interns and residents on identification by their hospital superintendents. Registration should be made with the Extension Program in Medicine, University of Kansas Medical Center, Kansas City 3, Kansas.

KENTUCKY

Sigma Xi Lecture.—Dr. Arnold L. Gesell, Yale University, New Haven, Conn., will deliver a lecture, to which the medical profession is invited, on "Human Infancy and the Ontogenesis of Behavior" at Halleck Hall, Louisville, March 22 at 8 p. m.

Personals.—Dr. John H. Blackburn of Bowling Green, who has completed fifty years as a medical practitioner, was guest of honor at a dinner sponsored by the Warren-Edmonson County Medical Society. The dinner was attended by sixty local physicians as well as by doctors from other parts of the state.——Dr. Annie S. Veech is, at her request, resigning as director of the Louisville-Jefferson County Board of Health and will act as associate director and consultant. From 1922 to 1937 Dr. Veech was on the staff of the Kentucky State Department of Health. She organized the first maternal and child health program in the state health department. Dr. Veech was born in Louisville and graduated from Woman's Medical College in Philadelphia.

MASSACHUSETTS

Hospital News.—Tor Court, the 155 acre Salisbury place, was transferred early December to Hillcrest Hospital, Pittsfield. It is the twenty-first Berkshire estate that has passed to an institutional corporation or state ownership.

Medical Alumni Meeting.—The Tufts Medical Alumni Association will hold its annual dinner meeting on April 6 at the Somerset Hotel, Boston. The guest speaker is to be Dr. Leonard A. Scheele, Surgeon General of the U. S. Public Health Service. Other speakers include Leonard Carmichael, LL.D., president of Tufts College, and Dr. Jacob L. Lochner Jr., Albany, N. Y., secretary, New York State Board of Registration in Medicine. Dr. Roy J. Heffernan will preside. The 25 year class will hold its reunion also on this date.

MICHIGAN

Cancer Day in Flint.—The Genesee County Medical Society is sponsoring a state wide conference at its fourth Annual Cancer Day program at Hurley Hospital, Flint, April 13 from 9:30 a. m. to 5 p. m. The program is as follows:

Arthur P. Stout, New York, Role of the Surgical Pathologist in Respect to the Cancer Problem.
Harold W. Dargeon, New York, Cancer in Children.
Thomas E. Jones, Cleveland, Cancer of the Lower Bowel—Present Status of Management.
Norman F. Miller, Ann Arbor, Management of Uterine Cancer.
E. W. Alton Ochsner, New Orleans, Basic Principles in Cancer Management.

NEW JERSEY

Director of Bureau of Laboratories.—The third of six bureau directors to be selected under the reorganization of the State Department of Health is Dr. A. J. Casselman, Camden, who will be director of the Bureau of Laboratories. Dr. Casselman has been associated with the Bureau of Venereal Disease Control since 1919, and has been chief of the division for the last two years. He will plan, organize and direct a central laboratory equipped to perform all laboratory services required by the New Jersey State Department of Health. He is a graduate of the University of Pennsylvania School of Medicine, Philadelphia, 1911.

NEW YORK

Courses in Surgery and Medicine.—Opportunities for postgraduate education in medicine and surgery are available at the Clifton Springs Sanitarium and Clinic at Clifton Springs. Physicians practicing within the region are eligible. The course in medicine, which runs for a period of one to four months, is under the direction of Dr. Bernard A. Watson, director of the Division of Medicine. All fields except brain surgery are available in the course in surgery under the direction of Dr. William C. Eikner, chief of Surgery Service.

Survey of Tuberculosis Hospitalization.—The New York Tuberculosis and Health Association has published a study based on the average year, 1947, when 2,373 tuberculosis patients left New York City hospitals against medical advice and before their disease had been arrested. Nearly half of the tuberculosis patients who "sign out" have open, infectious disease. The cost of caring for a tuberculous patient is estimated at $7.50 per day per patient, the amount paid by the city to private hospitals for such care. On this basis the "sign out" group alone, each patient averaging 365 hospital days, costs $6,531,682.50 per year.

The cost of public relief for the group and their dependents amounted to $2,134,800. Three city institutions and one in New Jersey were the subject of intensive study. There are twenty-one tuberculosis hospitals in the metropolitan area.

Clinic for Corneal Disorders.—A clinic for diagnosis and treatment of corneal disorders has been established at the Manhattan Eye, Ear and Throat Hospital, 210 East 64th Street, New York, as a cooperative undertaking sponsored by the Eye Bank for Sight Restoration and the hospital. The clinic meets at 9:30 a. m. Wednesday mornings. Patients are referred to this clinic from the other eye services of the Manhattan Eye, Ear and Throat Hospital, from other physicians, from public health organizations and from some of the national and state societies for the prevention of blindness. Most of the patients are charity cases and a great portion of the burden of financing is carried by the eye bank.

Personals.—Dr. Harold H. Berman, Ogdensburg, has been appointed director of the Willowbrook State School on Staten Island, the newest state institution for the mentally defective. Dr. Berman has been on the staff of the St. Lawrence State Hospital in Ogdensburg since 1926 and assistant director since 1938. He is a graduate of Tufts College Medical School, Boston, 1925.——Dr. James J. Quinlivan, Albany, has been appointed permanent assistant director of local health administration in the New York State Department of Health's division of local health service. Dr. Quinlivan has served as acting director since last March. He was formerly district health officer at Saranac Lake, Rochester and Amsterdam and a district health officer in Amsterdam and Johnstown.——Dr. George C. Vogt, Binghamton, has been elected chairman of the medical grievance committee of the State Department of Education, replacing Dr. Roy Upham, New York, who is retiring.——Dr. Ruth Gilbert, who has been in charge of the Diagnostic Laboratories, New York State Department of Health, since 1921 retired January 15.——Dr. Robert L. Ellithorp resigned as health commissioner of Gloversville after thirty years of association with the city health department.——Dr. John K. Meneely Jr., who has been on the staff of Albany Hospital and was made medical director there last December, has been appointed assistant dean of Albany Medical College, and Dr. Thomas Hale Jr. has been appointed associate dean. Dr. Meneely received his medical degree from Yale University School of Medicine, New Haven, Conn. Dr. Hale has been assistant dean at the Albany Medical College since 1943.

New York City

Perrin Long to Give Memorial Lecture.—Dr. Perrin H. Long, professor of preventive medicine at Johns Hopkins Hospital, Baltimore, will deliver the third annual Samuel Strausberg Memorial Lecture, sponsored by the Clinical Society of Beth-El Hospital, on April 26, 8:30 p. m. His subject will be "Clinical Use of Aureomycin, Chloromycetin, Polymyxin and Other New Antibiotics." The lecture will be delivered at the Kings County Medical Society Building, 1313 Bedford Avenue, Brooklyn.

Children's Psychiatric Clinic.—A clinic to provide psychiatric counseling and treatment for emotionally disturbed children as well as their parents recently opened in Brooklyn as an adjunct of the Council Child Development Center in Manhattan. It is aimed at helping pre-school-age Brooklyn children. The clinic will operate on a grant received from the New York State Department of Mental Hygiene, consisting of federal funds allocated by the U. S. Public Health Service for the development of community health service for children.

Institute of Cancer Research.—The Columbia-Presbyterian Medical Center is establishing an Institute of Cancer Research to be staffed by cancer specialists. It is being developed primarily to bring about an integration of the activities in numerous medical sciences concerned with cancer research. Two new major cancer units at the center will be completed during 1949 and 1950. Additions are three new floors of cancer research laboratories atop the Vanderbilt Clinic and the Francis Delafield Hospital being erected at the center by the city. Another research division to be included will be the facilities and personnel of the department of cancer research, which was moved to the College of Physicians and Surgeons in 1938 from the Columbia campus on Morningside Heights. Dr. Cushman D. Haagensen, coordinator of cancer teaching at the Columbia University College of Physicians and Surgeons, has been appointed director of the institute. An associate professor of clinical surgery, Dr. Haagensen has had training in cancer as pathologist, surgeon and investigator. He is assistant attending surgeon and assistant surgical pathologist to Presbyterian Hospital. A coordinating committee has been appointed composed of professors and executive officers of the departments of biochemistry, medicine, obstetrics and gynecology, pathology, pharmacology, radiology and surgery.

PENNSYLVANIA

Special Society Meeting.—The annual meeting of the Pennsylvania Academy of Ophthalmology and Otolaryngology will be held April 22-24 at the Penn Harris Hotel, Harrisburg. Among the speakers who will present papers are Drs. Albert D. Ruedemann, Detroit; John R. Lindsay, Chicago; Ralph O. Rychener, Memphis, Tenn.; Carlton S. Nash, Rochester, N. Y.; Jay G. Linn, Pittsburgh; Arno E. Town, New York, and George M. Coates, Philadelphia. The meeting will also include a round table discussion on "Headaches" which will include representatives of all major specialties. There will be a study club to discuss "Cataract Problems."

Philadelphia

Alumni Society Opened to Women.—After fifty-seven years of existence as a men's club, the Philadelphia Alumni Society of the medical department of the University of Pennsylvania decided at its annual meeting on February 19 to welcome as members women graduates of the medical department.

Resolution on Local Water Problem.—The Philadelphia County Medical Society has sent a resolution to Mayor Samuel of Philadelphia expressing its concern over the city water supply, which they designated as unpalatable, ill-smelling and not wholly healthful. It urged that Philadelphia take steps to insure its early, complete and lasting correction.

City Health Survey.—A broad survey of the city's medical and health services and needs began February 19 under the sponsorship of the city's department of public health, the City Planning Commission, the Health and Welfare Council, the Philadelphia County Medical and the Dental societies, the Board of Public Education, the Bureau of Municipal Research and others. Dr. William H. Perkins, dean of Jefferson Medical College, is chairman of the executive committee. Every Philadelphia mother of a 1 year old child will be requested to answer a questionnaire covering the type and frequency of prenatal and postnatal medical care that her child received and by whom such care was rendered.

SOUTH CAROLINA

Laboratory for Study of Radioisotopes.—The Medical College of the State of South Carolina, Charleston, has established a laboratory for the study and use of radioisotopes. The laboratory is under the direction of Dr. Robert B. Taft, professor of radiology; the advisory committee consists of Drs. William M. McCord, professor of chemistry, Frederick E. Kredel, professor of surgery, and Theodore G. Bernthal, professor of physiology.

State Health Council Chartered.—The South Carolina Health Council, designed to strengthen and develop a full health program for the state, was granted a charter February 17. Organized in Florence, the council lists Dr. Harold S. Gilmore of Nichols as chairman, M. L. Meadors of Florence, secretary, and R. L. Dougherty of Columbia, treasurer. It will serve as a clearing house on health and medical care problems and programs, will stimulate creation of local health councils and support specific health programs.

TENNESSEE

Dr. Rolfe Honored.—A testimonial assembly was held at the Meharry Medical College, Nashville, Tenn., January 8 to honor Dr. Daniel T. Rolfe, professor of physiology and chairman of the department of physiology and pharmacology at the college. Dr. Rolfe came to Meharry in 1930. When the department of physiology and pharmacology were combined, he was made chairman.

American Museum of Atomic Energy.—The Oak Ridge Institute of Nuclear Studies has established the world's first permanent museum dealing with atomic energy, to be known as the American Museum of Atomic Energy. The exhibit will be open to the public March 19 when the security gates of the town of Oak Ridge are removed and the community adopts a normal residential and business role. The museum will be operated by the institute, a nonprofit educational corporation of nineteen Southern universities which conducts a program of research and training in nuclear sciences under contract with the Atomic Energy Commission. The display will be housed in a 32,000 square foot structure used as a cafeteria during the war. A small admission charge will be made. William G. Pollard, Ph.D., executive director of the institute, said that "the need for broadening our program to include public education has been apparent for some time."

TEXAS

Dallas Health Museum Award.—Nominations for the 1949 Dallas Health Museum award for outstanding contributions to public health in Texas will be accepted until April 15. They should be submitted to the museum, where they will be reviewed by a board of judges appointed by museum officials.

Personal.—Dr. Charles H. Harris of Harris Memorial Methodist Hospital, Fort Worth, was among eight persons who recently were named to membership in the newly established Methodist Hall of Fame in Philanthropy. He received a hand-engrossed membership certificate from the Board of Hospitals and Homes of the Methodist Church. The honor is bestowed for outstanding contribution of time, talent and money to Methodist philanthropic institutions.

GENERAL

Orthopsychiatric Association Meeting.—The American Orthopsychiatric Association will hold its annual meeting at the Hotel Stevens, Chicago, April 4-6, under the presidency of Samuel J. Beck, Ph.D., Chicago. The general session theme will be "Education for Emotional Insight in a World in Crisis."

National Negro Health Week.—The thirty-fifth annual observance of National Negro Health Week has been scheduled for April 3-10 with the objective to "cooperate with your health agencies and your neighbors for better health and sanitation in your community." A day by day schedule of activities has been made up by the U. S. Public Health Service

Instruction in Standard Nomenclature.—Basic instruction in Standard Nomenclature through lecture and practice will be a major feature of the Institute for Medical Record Librarians at Buck Hill Falls Inn, Buck Hill Falls, Pa., April 4-8. The Pennsylvania Association of Medical Record Librarians and the Hospital Association of Pennsylvania are sponsors.

Mental Hospital Institute.—The American Psychiatric Association is sponsoring a Mental Hospital Institute in Philadelphia April 11-15. In a drive to improve mental hospital services in the United States and Canada, the institute will draw together several hundred professional and lay leaders for an attack on the problem. Enrolment in the institute is open to public and private hospital staff members and to doctors and laymen in the United States and Canada. It will be under the direction of Dr. Daniel Blain, medical director of the association. The fee for the institute is $50.

Society Elections.—The National Society for Medical Research at its recent annual meeting in Chicago reelected two Chicagoans, Anton J. Carlson, Ph.D., president, and Dr. Andrew C. Ivy, secretary-treasurer.——The Mid-South Postgraduate Medical Assembly at its recent annual meeting installed Dr. Hoyt R. Allen of Little Rock, Ark., as president and chose Dr. Julian G. Price, Dyersburg, Tenn., president-elect.——Officers of the South Atlantic Association of Obstetricians and Gynecologists for the year 1949-1950 are Dr. Charles J. Andrews, Norfolk, Va., president; Dr. Lester A. Wilson, Charleston, S. C., president-elect, and Dr. Emmett D. Colvin, Atlanta, Ga., secretary-treasurer. The next annual meeting will be held at the Hotel Roanoke, Roanoke, Va., Feb. 9-11, 1950.

Four Openings for Visiting Professors in Burma.—The Department of State has recently announced four openings under the Fulbright Educational Exchange Program for visiting professors to teach at the Medical College of the University of Rangoon in Burma beginning in July 1949. The openings are for one academic year and include the fields of orthopedic surgery; eye, ear, nose and throat surgery; dentistry, and public health. One opening is also offered for advanced research in public health. A grant payable in Burmese currency is offered in connection with each opening. Each grant includes stipend, round trip transportation, a maintenance allowance and an allowance for books or equipment essential to the assignment. Requests for further information should be addressed to the Conference Board of Associated Research Councils, Committee on International Exchange of Persons, 2101 Constitution Avenue, Washington 25, D. C.

Meeting on Voluntary Medical Care.—The Council of the New England State Medical Societies will hold a meeting March 27 beginning at 1:30 p. m. at the Copley Plaza, Boston, on voluntary medical care plans in the region. County medical society officers and committee members are also invited to the meeting. Delegates from the six state members will report on "Extending Medical Care in New England through Medical Society Sponsored Voluntary Plans." Mr. Henry D. Locke, research director, Liberty Mutual Insurance Company, Boston, will speak on extending medical care through insurance company programs. Discussion will follow. The meeting will open with a discussion of the national education campaign of the American Medical Association by Mr. Clem Whitaker, campaign director and Leone Baxter, general manager of the campaign. Dr. James R. Miller, Hartford, Conn., will speak on "The Special A. M. A. Assessment."

Dr. Diamond Named Medical Director of Red Cross Blood Program.—At the request of the Committee on Medical Sciences of the Research and Development Board of the National Military Establishment under the auspices of the National Research Council, the National Institutes of Health and the American Red Cross, many researchers in the fields of preservation and use of blood and blood derivatives met recently at the Harvard Medical School in Boston. Particularly stressed were the new developments in the collection, preservation and administration of whole blood and its component parts. The discussions brought out that the American Red Cross, through its National Blood Program, is in excellent position to put into practice many of the recommendations made by medical scientists in this field.

Dr. Louis K. Diamond of Boston has been appointed medical director of the Red Cross National Blood Program. He will be on temporary leave of absence from the Children's Medical Center, Boston, and the department of pediatrics at Harvard Medical School while serving in his new capacity. Dr. Diamond was an investigator dealing with blood transfusion problems for the National Research Council during the war. He has been director of several blood banks and of the Blood Grouping Laboratory of Boston.

Conference on the Nervous System.—A conference on development, growth and regeneration of the nervous system is to be held by the International Union of Biological Sciences at the University of Chicago, March 21-25. A final summary meeting on March 25 will be open to all interested scientists. Subjects to be discussed include differentiation of the central nervous system, nerve fiber orientation and patterns, physiology of neuron growth, peripheral and central nerve regeneration, problems of specificity and selectivity and neural growth and the development of behavior.

Foreign participants in the meeting, which is sponsored by UNESCO and the Rockefeller Foundation, are J. Boeke, Utrecht; Holger Hyden, Stockholm; Rita Levi-Montalcini, Torino; Alberto Stefanelli, Rome; Sydney Sunderland, Melbourne, and John Z. Young, London. American members taking part are D. H. Barron, Ph.D., Yale University, New Haven; David Bodian, Johns Hopkins University, Baltimore; Samuel R. Detwiler, Ph.D., Columbia University, New York; Dr. Louis B. Flexner, Carnegie Institution, Baltimore; Dr. Ralph W. Gerard, University of Chicago; Viktor Hamburger, Ph.D., Washington University, St. Louis; Davenport Hooker, Sc.D., University of Pittsburgh; Dr. Warren H. Lewis, Wistar Institute, Philadelphia; Francis O. Schmitt, Ph.D., Massachusetts Institute of Technology, Cambridge; Carl C. Speidel, Sc.D., University of Virginia, Charlottesville; Roger W. Sperry, Ph.D., University of Chicago; Paul A. Weiss, Ph.D., University of Chicago, and William F. Windle, Sc.D., University of Pennsylvania.

Marriages

John William Hillman, Emory, Va., to Miss Virginia Swindler of Springfield, Mo., in Baltimore, January 16.

William Getz Thuss Jr., Birmingham, Ala., to Miss Gene Bradley Connell of Chattanooga, Tenn., January 22.

Herman Winkelman, Scotia, N. Y., to Miss Phyllis Wheeler of Cobleskill, in Elmira, December 24.

Harrison J. Brownlee, Pierrepont Manor, N. Y., to Miss Anne Sutton McNeil of Dallas, Pa., October 30.

John F. Lewis Jr., Hoboken, N. J., to Miss Margaret June Murphy in Union City, N. J., January 22.

Alfred Guerin Allen, San Francisco, to Miss Cora Elizabeth Robinson of Churchill, Md., recently.

Billy Booth Brinkley, Bristol, Tenn., to Miss Sarah Eunice Legate at Lexington, Miss., January 16.

Clarence F. Webb, Grand Rapids, Mich., to Miss Maxine Mueller, in Dwight, Ill., recently.

Samuel L. Parker Jr., to Miss Frances Carr, both of Durham, N. C., recently.

Francis Philip Bilello to Miss Jeanne Grace Liota, both of Brooklyn, January 9.

The cost of public relief for the group and their dependents amounted to $2,134,800. Three city institutions and one in New Jersey were the subject of intensive study. There are twenty-one tuberculosis hospitals in the metropolitan area.

Clinic for Corneal Disorders.—A clinic for diagnosis and treatment of corneal disorders has been established at the Manhattan Eye, Ear and Throat Hospital, 210 East 64th Street, New York, as a cooperative undertaking sponsored by the Eye Bank for Sight Restoration and the hospital. The clinic meets at 9: 30 a. m. Wednesday mornings. Patients are referred to this clinic from the other eye services of the Manhattan Eye, Ear and Throat Hospital, from other physicians, from public health organizations and from some of the national and state societies for the prevention of blindness. Most of the patients are charity cases and a great portion of the burden of financing is carried by the eye bank.

Personals.—Dr. Harold H. Berman, Ogdensburg, has been appointed director of the Willowbrook State School on Staten Island, the newest state institution for the mentally defective. Dr. Berman has been on the staff of the St. Lawrence State Hospital in Ogdensburg since 1926 and assistant director since 1938. He is a graduate of Tufts College Medical School, Boston, 1925.——Dr. James J. Quinlivan, Albany, has been appointed permanent assistant director of local health administration in the New York State Department of Health's division of local health service. Dr. Quinlivan has served as acting director since last March. He was formerly district health officer at Saranac Lake, Rochester and Amsterdam and a district health officer in Amsterdam and Johnstown.——Dr. George C. Vogt, Binghamton, has been elected chairman of the medical grievance committee of the State Department of Education, replacing Dr. Roy Upham, New York, who is retiring.——Dr. Ruth Gilbert, who has been in charge of the Diagnostic Laboratories, New York State Department of Health, since 1921 retired January 15.——Dr. Robert L. Ellithorp resigned as health commissioner of Gloversville after thirty years of association with the city health department.——Dr. John K. Meneely Jr., who has been on the staff of Albany Hospital and was made medical director there last December, has been appointed assistant dean of Albany Medical College, and Dr. Thomas Hale Jr. has been appointed associate dean. Dr. Meneely received his medical degree from Yale University School of Medicine, New Haven, Conn. Dr. Hale has been assistant dean at the Albany Medical College since 1943.

New York City

Perrin Long to Give Memorial Lecture.—Dr. Perrin H. Long, professor of preventive medicine at Johns Hopkins Hospital, Baltimore, will deliver the third annual Samuel Strausberg Memorial Lecture, sponsored by the Clinical Society of Beth-El Hospital, on April 26, 8:30 p. m. His subject will be "Clinical Use of Aureomycin, Chloromycetin, Polymyxin and Other New Antibiotics." The lecture will be delivered at the Kings County Medical Society Building, 1313 Bedford Avenue, Brooklyn.

Children's Psychiatric Clinic.—A clinic to provide psychiatric counseling and treatment for emotionally disturbed children as well as their parents recently opened in Brooklyn as an adjunct of the Council Child Development Center in Manhattan. It is aimed at helping pre-school-age Brooklyn children. The clinic will operate on a grant received from the New York State Department of Mental Hygiene, consisting of federal funds allocated by the U. S. Public Health Service for the development of community health service for children.

Institute of Cancer Research.—The Columbia-Presbyterian Medical Center is establishing an Institute of Cancer Research to be staffed by cancer specialists. Dr. Diamond was an investigator dealing with blood transfusion problems for the National Research Council during the war. He has been director of several blood banks and of the Blood Grouping Laboratory of Boston.

Conference on the Nervous System.—A conference on development, growth and regeneration of the nervous system is to be held by the International Union of Biological Sciences at the University of Chicago, March 21-25. A final summary meeting on March 25 will be open to all interested scientists. Subjects to be discussed include differentiation of the central nervous system, nerve fiber orientation and patterns, physiology of neuron growth, peripheral and central nerve regeneration, problems of specificity and selectivity and neural growth and the development of behavior.

Foreign participants in the meeting, which is sponsored by UNESCO and the Rockefeller Foundation, are J. Boeke, Utrecht; Holger Hyden, Stockholm; Rita Levi-Montalcini, Torino; Alberto Stefanelli, Rome; Sydney Sunderland, Melbourne, and John Z. Young, London. American members taking part are D. H. Barron, Ph.D., Yale University, New Haven; David Bodian, Johns Hopkins University, Baltimore; Samuel R. Detwiler, Ph.D., Columbia University, New York; Dr. Louis B. Flexner, Carnegie Institution, Baltimore; Dr. Ralph W. Gerard, University of Chicago; Viktor Hamburger, Ph.D., Washington University, St. Louis; Davenport Hooker, Sc.D., University of Pittsburgh; Dr. Warren H. Lewis, Wistar Institute, Philadelphia; Francis O. Schmitt, Ph.D., Massachusetts Institute of T [illegible] arl C. Speidel, Sc.D., University of [illegible] oger W. Sperry, Ph.D., University of [illegible] Ph.D., University of Chicago, and William F. Windle, Sc.D., University of Pennsylvania.

Marriages

John William Hillman, Emory, Va., to Miss Virginia Swindler of Springfield, Mo., in Baltimore, January 16.

William Getz Thuss Jr., Birmingham, Ala., to Miss Gene Bradley Connell of Chattanooga, Tenn., January 22.

Herman Winkelman, Scotia, N. Y., to Miss Phyllis Wheeler of Cobleskill, in Elmira, December 24.

Harrison J. Brownlee, Pierrepont Manor, N. Y., to Miss Anne Sutton McNeil of Dallas, Pa., October 30.

John F. Lewis Jr., Hoboken, N. J., to Miss Margaret June Murphy in Union City, N. J., January 22.

Alfred Guerin Allen, San Francisco, to Miss Cora Elizabeth Robinson of Churchill, Md., recently.

Billy Booth Brinkley, Bristol, Tenn., to Miss Sarah Eunice Legate at Lexington, Miss., January 16.

Clarence F. Webb, Grand Rapids, Mich., to Miss Maxine Mueller, in Dwight, Ill., recently.

Samuel L. Parker Jr., to Miss Frances Carr, both of Durham, N. C., recently.

Francis Philip Bilello to Miss Jeanne Grace Liota, both of Brooklyn, January 9.

Deaths

John Bramwell Davis, Denver; born in Indianapolis, Nov. 4, 1874; Gross Medical College, Denver, 1902; past president of the Denver Clinical and Pathological Society; member of the American Medical Association; member of the American Urological Association and past president of the South Central Section; fellow of the American College of Surgeons; formerly on the faculty of the University of Colorado School of Medicine; specialist certified by the American Board of Urology, Inc.; served as a member and secretary-treasurer of the state board of medical examiners; consulting urologist for Selective Service during World Wars I and II; affiliated with the Denver and Colorado general hospitals, Children's Hospital, Mercy Hospital and St. Luke's Hospital, where he died December 23, aged 74, of pulmonary edema.

Basil R. Beltran ⊕ Philadelphia; born in New Orleans in 1889; Medico-Chirurgical College of Philadelphia, 1912; associate professor of surgery at the Medico-Chirurgical College, Graduate School of Medicine, University of Pennsylvania; received the Palme-Academic decoration of the Ministry of National Education of France for services rendered to the French during World War I and to the French in Philadelphia; served as medical director and chief surgeon of the Eastern State Penitentiary, chief and chairman of the staff of the Nazareth Hospital; affiliated with the Misericordia and Fitzgerald Mercy hospitals; died January 19, aged 59, of hypertension and cardiac failure.

Louis Rudolph ⊕ Chicago; born in Racine, Wis., in 1886; Northwestern University Medical School, Chicago, 1911; specialist certified by the American Board of Obstetrics and Gynecology, Inc.; member of the Central Association of Obstetricians and Gynecologists and Chicago Gynecological Society; fellow of the American College of Surgeons; served on the faculty of Loyola University School of Medicine; professor of obstetrics at Cook County Graduate School of Medicine; affiliated with Mount Sinai and Cook County hospitals; died in Wesley Memorial Hospital January 29, aged 63, of acute hepatitis and acute pancreatitis.

Kasimir Ambrose Zurawski, Chicago; born in Poland Dec. 20, 1871; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1899; in 1913 member of the House of Delegates of the American Medical Association; at one time on the faculty of his alma mater; spent several years in Poland improving health conditions in that country and served as minister of health under the Pilsudzki government; decorated by the Polish government and awarded an honorary degree by the University of Warsaw; died in St. Luke's Hospital January 24, aged 77.

Paul Appleton ⊕ Providence, R. I.; Harvard Medical School, Boston, 1915; specialist certified by the American Board of Obstetrics and Gynecology; member of the New England Obstetrical and Gynecological Society; fellow of the American College of Surgeons; served during World War I; on the staff of the Providence Lying-in Hospital; died December 24, aged 61, of myocardial infarction.

Joseph Henry Cahoon, Middletown, Del.; University of Maryland School of Medicine, Baltimore, 1903; died in the Delaware Hospital December 12, aged 83, of arteriosclerosis.

Hanna L. Caldwell, Miami, Fla.; Bennett Medical College, Chicago, 1904; died December 6, aged 79.

Miles Dudley Chisholm ⊕ Westfield, Mass.; University College of Medicine, Richmond, 1900; fellow of the American College of Surgeons; served during World War I; formerly city physician; served on the staff of the Noble Hospital; died December 19, aged 71, of coronary disease.

Herman Vascoe Collins, Monroe, La.; Atlanta School of Medicine, 1911; member of the American Medical Association; died December 2, aged 66, of carcinoma of the small intestine.

Perry E. Cotton ⊕ Elwood, Ind.; Indiana University School of Medicine, Indianapolis, 1934; died November 29, aged 40, of injuries received when the automobile in which he was driving was struck by a train.

Charles Wellington Craik, Venice, Calif.; University Medical College of Kansas City, 1900; served during World War I; died in the Veterans Administration Center, Los Angeles, in December, aged 76.

Hugh G. Dallas, Jefferson City, Mo.; St. Louis College of Physicians and Surgeons, 1908; died in St. Mary's Hospital December 8, aged 65.

Emory Francis Davis, Springfield, Ohio; Medical College of Ohio, Cincinnati, 1897; member of the American Medical Association; died December 25, aged 78, of pulmonary embolism and carcinoma of the cecum.

John Diven ⊕ Philadelphia; University of Pennsylvania School of Medicine, Philadelphia, 1912; died in Wilmington, Del., December 16, aged 65.

Monica Donovan ⊕ San Francisco; Stanford University School of Medicine, San Francisco, 1917; member of the American Roentgen Ray Society and of the Radiological Society of North America; formerly on the faculty of her alma mater; medical advisor to the San Francisco College for Women; affiliated with St. Mary's Hospital; died December 29, aged 57.

Theodore Jordan Drisdel, Greenfield, Mo.; St. Louis University School of Medicine, 1905; served during World War I; died December 7, aged 68, of heart disease.

Fred Conrad Enander ⊕ New Britain, Conn.; Tufts College Medical School, Boston, 1922; died December 21, aged 51.

Julius Ernest Fleischner ⊕ Chicago; University of Illinois College of Medicine, Chicago, 1923; served during World War I; affiliated with the Loretto and Garfield Park Community hospitals; died in River Forest, Ill., December 26, aged 51, of arteriosclerotic heart disease.

Gustav Adolphus Floreth ⊕ Mount Olive, Ill.; Marion-Sims-Beaumont Medical College, St. Louis, 1903; served overseas during World War I; for many years member of the board of education; died December 23, aged 71, of coronary thrombosis.

Gilbert E. Frank, Harbor Springs, Mich.; Detroit College of Medicine, 1901; member of the American Medical Association; died in St. Johns, December 20, aged 69, of lymphosarcoma.

Christopher C. Gaard ⊕ Bremerton, Wash.; St. Louis University School of Medicine, 1920; died in the Harrison Memorial Hospital December 16, aged 60, of carcinomatosis.

Parker Blair Gamble, Detroit; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1913; member of the American Medical Association; served on the staff of Parkside Hospital; died December 27, aged 62, of coronary thrombosis, hypertension and arteriosclerosis.

Leroy Clarence Green, Ashville, N. Y.; University of Buffalo School of Medicine, 1895; member of the American Medical Association; since 1919 health officer of the town of North Harmony; died December 29, aged 77, of paralysis agitans.

Francis Preston Gudgell, Owingsville, Ky.; University of Louisville Medical Department, 1882; member of the American Medical Association; died in the Good Samaritan Hospital, Lexington, December 25, aged 88.

Erwin Kroll Gutmann, Jersey City, N. J.; Cornell University Medical College, New York, 1929; member of the American Medical Association; served overseas during World War II; died December 21, aged 44, of coronary thrombosis.

Tryggve Alexander Hagerup, Dodgeville, Wis.; Friedrich-Wilhelms-Universität Medizinische Fakultät, Berlin, Prussia, 1920; member of the American Medical Association; past president of the Iowa County Medical Society; died December 17, aged 55, of acute atrophy of the liver.

Robert Clarence Hannigen, Amesbury, Mass.; Medical School of Maine, Portland, 1901; member of the American Medical Association; served during World War I; died in the Amesbury Hospital December 16, aged 71, of cerebral thrombosis.

Hugh Henry Hanrahan ⊕ Rutland, Vt.; University of Vermont College of Medicine, Burlington, 1915; died December 14, aged 61, of myocarditis.

Hiram Abiff Haskell, Windsor, Calif.; Northwestern University Medical School, Chicago, 1899; served with the British Army during World War I; died December 25, aged 86, of injuries received when struck by an automobile.

Carl John Hawley ⊕ Burbank, Calif.; University of Southern California School of Medicine, Los Angeles, 1935; served during World War II; died in the Veterans Administration Hospital, Van Nuys, December 26, aged 44, of hypertension and cerebral hemorrhage.

Ralph H. Herbert, La Crosse, Wis.; Bennett Medical College, Chicago, 1900; died in La Crosse Hospital, December 24, aged 70, of cerebral hemorrhage.

Frank McElroy Huntoon, Syracuse, N. Y.; Cornell University Medical College, New York, 1903; member of the Society of American Bacteriologists; formerly on the faculty of his alma mater; at one time senior bacteriologist and medical director, H. K. Mulford Company in Glen Olden, Pa.; served during World War I; died in the Onondaga Sanatarium, December 21, aged 67, of pulmonary tuberculosis.

Alfred Edward Jones, Chicago; University of Illinois College of Medicine, Chicago, 1915; member of the American Urological Association; fellow of the American College of Surgeons; specialist certified by the American Board of Urology; formerly on the faculty of Loyola University School of Medicine; served during World War II; affiliated with Michael Reese Hospital; died November 10, aged 58, of chronic myocarditis.

Weston William Lasher, Saxonburg, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1893; member of the American Association of Industrial Physicians and Surgeons; died in the Allegheny Valley Hospital, Tarentum, December 12, aged 77, of leukemia.

Leonard Frank Lauf, Columbus, Ohio; Jefferson Medical College of Philadelphia, 1907; member of the American Medical Association; died December 16, aged 65, of hypertension.

Hugh Francis Lena ⊕ New London, Conn.; Johns Hopkins University School of Medicine, Baltimore, 1916; past president of the New London County Medical Society; fellow of the American College of Surgeons; served during World War I; owner of Dr. Lena's Surgical Hospital; died November 8, aged 60, of coronary occlusion.

Roy Chester Lowe, Neenah, Wis.; the Hahnemann Medical College and Hospital, Chicago, 1906; member of the American Medical Association; past president of the Winnebago County Medical Society; died in the Theda Clark Hospital December 16, aged 65.

William Douglas Macon, Charlottesville, Va.; University of Virginia Department of Medicine, Charlottesville, 1897; member of the American Medical Association; resigned in 1924 as professor of obstetrics at his alma mater, where he had been clinical instructor in anesthesia in 1904 and in the following year also in the practice of medicine; served as health officer for the city of Charlottesville; died December 30, aged 79, of carcinoma.

Fred E. Murphy, Traverse City, Mich.; Detroit College of Medicine, 1906; died in the University Hospital, Ann Arbor, December 1, aged 71, of carcinoma of the pancreas with metastases.

Clyde Clark Neese ⊕ Wilmington, Del.; Temple University School of Medicine, Philadelphia, 1917; member of American Proctological Society; served during World War I; died in the Wilmington General Hospital December 5, aged 60, of congestive heart disease.

David Stanislaus O'Donnell, Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia 1905; served during World War I; affiliated with St. Joseph's Hospital, where he died December 23, aged 68.

John Joseph O'Loughlin, Howard Beach, N. Y.; Fordham University School of Medicine, New York, 1918; served during World War I; member of the American Medical Association; died December 14, aged 55, of cerebral hemorrhage.

William Robert Orr, Helena, Ark.; Tulane University of Louisiana School of Medicine, New Orleans, 1908; died in Helena Hospital December 1, aged 65, of injuries received in an explosion on a river cruiser.

Michelangelo Pacella, Waukegan, Ill.; Chicago Medical School, 1922; died in St. Theresa Hospital December 11, aged 78, of chronic nephritis and pneumonia.

Lovick Edward Peacock, West Blocton, Ala.; Medical College of Alabama, Mobile, 1892; member of the American Medical Association; died December 23, aged 78, of bronchogenic carcinoma.

Edward August Peterson, Vallejo, Calif.; Medical Department of the University of California, San Francisco, 1907; served overseas during World War I; formerly on the staff of Vallejo General Hospital; died in Napa, December 9, aged 67, of heart disease.

Austin Flint Philpott, Fort Madison, Iowa; St. Louis College of Physicians and Surgeons, 1903; died in the Sacred Heart Hospital December 20, aged 67, of chronic nephritis.

Theodore A. Pierson, Hopewell, N. J.; College of Physicians and Surgeons, Baltimore, 1894; member of the American Medical Association; served three terms as mayor of Hopewell and as president of the board of education; director of the Hopewell National Bank; died December 24, aged 78, of gallbladder disease.

Pierre Celestin Pilon, Minneapolis; School of Medicine and Surgery of Montreal, Canada, 1886; served during World I; formerly mayor of Paynesville and coroner of Stearns County; died in St. Mary's Hospital December 16, aged 84.

Lewis R. Polk ⊕ Memphis, Tenn.; Memphis Hospital Medical College, 1909; died December 18, aged 63, of cerebral hemorrhage and hypertension.

Lorne McDonnell Ryan, Madison, Conn.; McGill University Faculty of Medicine, Montreal, Canada, 1905; member of the American Medical Association and of the Medical Society of the State of New York; fellow of the American College of Surgeons; affiliated with St. Peter's Hospital in Brooklyn; consulting surgeon to St. Anthony's Hospital in Woodhaven, N. Y.; died December 30, aged 67, of coronary thrombosis.

Raymond St. Clair, Sonoma, Calif.; College of Physicians and Surgeons, Keokuk, Iowa, 1896; past president of the Nevada State Medical Association; died November 30, aged 78.

Michael Abdallah Saleeby, Dillon, S. C.; Medical College of the State of South Carolina, Charleston, 1917; died in the McLeod Infirmary, Florence, December 29, aged 55, of coronary thrombosis.

Walter Howard Sanford, New York; Albany (N. Y.) Medical College, 1899; recently retired as pathologist at the Manhattan State Hospital; died December 13, aged 70, of angina pectoris.

Preston Pope Satterwhite, Great Neck, N. Y.; Bellevue Hospital Medical College, New York, 1898; died in the Harkness Pavilion, New York, December 27, aged 80.

Abe Lewis Scheff, Birmingham, Ala.; Vanderbilt University School of Medicine, Nashville, Tenn., 1916; served during World Wars I and II; formerly passed assistant surgeon in the U. S. Public Health Service, reserves; at one time director of the Santa Cruz (Ariz.) Health Service; affiliated with the Veterans Administration; died December 17, aged 54, of coronary thrombosis.

Harry M. Schuffell ⊕ Canton, Ohio; Western Reserve University Medical Department, Cleveland, 1893; fellow of the American College of Surgeons; specialist certified by the American Board of Surgery; consulting surgeon at the Mercy Hospital, where he was chief of staff for many years; on the medical board of the Aultman Hospital; died in Orlando, Fla., December 22, aged 82, of arteriosclerotic heart disease.

Mosé Scuccimarra, Peekskill, N. Y.; Fordham University School of Medicine, New York, 1919; member of the American Medical Association; examining physician for the Selective Service Board during World War II; died in the Memorial Hospital, New York, December 26, aged 65.

Zebidee Lafayett Shipley, Cookeville, Tenn.; Chattanooga Medical College, 1902; member of the American Medical Association; died November 14, aged 75, of cerebral thrombosis.

James H. Shipper, Martinsburg, W. Va.; Baltimore University School of Medicine, 1897; at one time member of the state board of health and city and county health officer; affiliated with the City Hospital and the King's Daughters' Hospital, where he died December 27, aged 84, of paralysis.

James Edward Smith ⊕ Rolla, Mo.; Tulane University of Louisiana School of Medicine, New Orleans, 1912; formerly associated with the U. S. Public Health Service; served as medical officer in charge of the U. S. Trachoma Hospital in Knoxville, Tenn., and the Missouri Trachoma Hospital in Rolla; died December 1, aged 60.

Don Carlos Stansberry, Hastings, Neb.; College Physicians and Surgeons, Keokuk, Iowa, 1890; died December 25, aged 87.

Samuel Cecil Stanton ⊕ Chicago; Northwestern University Medical School, Chicago, 1892; an Affiliate Fellow of the American Medical Association; served during the Spanish-American War and World War I; formerly consulting medical director of the Federal Reserve Life Insurance Company and medical director of the Farmers National Life Insurance Company of America; died January 26, aged 92, of cerebral thrombosis and diabetes mellitus.

Jacob Erhard Steimen, Boston; College of Physicians and Surgeons, Boston, 1907; died November 15, aged 76, of coronary occlusion.

David Thomson ⊕ Burbank, Calif.; Rush Medical College, Chicago, 1914; affiliated with the Physicians and Surgeons Hospital in Glendale; died recently, aged 65, of coronary occlusion.

Sara Elise Wise, Los Angeles; Hahnemann Hospital College of San Francisco, 1893; College of Physicians and Surgeons, Boston, 1894; died in December, aged 83.

Foreign Letters

PARIS

Research in French Universities

ANTIHISTAMINES

B. N. Halpern, who studied the first antihistamine substance used therapeutically (antergan® [dimethylamino-ethyl benzylaniline]) is still actively working on this subject. With his collaborator, Reber, he has just discovered a phenomenon of which the practical consequences have not yet been appreciated. The edema of local infection, provoked in the body of an animal by subcutaneous injection of Salmonella typhimurium or of Staphylococcus, is inhibited by certain antihistamines such as "phenergan." There is a remarkable contrast between such animals treated or not treated by the antihistamine substance: (*a*) in animals infected with subcutaneous injection of the aforementioned germs, but without "phenergan," no deaths occurred; (*b*) in 80 per cent of animals infected in the same conditions and treated with "phenergan" complications developed, septicemia and visceral abscesses, which terminated in death. It is assumed that these complications occurred because the antihistamine in preventing local edema thus destroyed a natural barrier to the diffusion of the infection through the bodies of the experimental animals. The important question—because of these results—is whether antihistamine substances are contraindicated during the development of local infections in man.

LEUKEMIA

Leukemia is being made the subject of vigorous active research. The cytologic studies undertaken particularly (among others) by Bessis and Dreyfus (Bessis, M.: Cytologic sanguine normale et pathologique, Paris, Mason & Cie., 1948; Bessis, M., and Dreyfus, B.: *Semaine d. hôp. Paris* 24:1739, 1948) have focused attention on two fundamental characteristics of the leukemic cells: (*a*) the phenomena of arrest of cellular maturation, and (*b*) the sudden appearance of more and more young forms in the developmental course of the disease; these characteristics are common to both cells of leukemia and sarcomatous cells. From a therapeutic point of view, the "exsanguinotransfusions" (Bernard, J., and Bessis, M.: *Bull. et mém. Soc. méd. Paris* 64:14, 1948) as well as large and repeated transfusions (Vallery-Radot; Hamburger, J.; Milliez, P.; Domart, A.; Dreyfus, B., and Barbizet, J.: *Semaine d. hôp. Paris* 24:1979, 1948) are capable of causing remissions of great theoretic interest, for they suggest the existence of antileukemic elements in the blood of normal persons.

ARTERITIS

The treatment of arteritis of the lower limbs by the intra-arterial injections of oxygen is being made the object of research by Lemaire, Loeper and Housset (Lemaire, A.; Loeper, J., and Housset, E., in Journées Therapeutiques de 1948, to be published). These workers administered 70 to 100 cc. of oxygen at each sitting under a pressure represented by the midpoint between the maximum and minimum arterial pressures. The treatment must be used exclusively for the lower limbs. The functional results, represented by a lessening or disappearance of intermittent claudication, appear generally good. The relieving of pain on walking, standing, etc., is of longer duration than that obtained by the traditional methods of treatment.

THE NETHERLANDS

AMSTERDAM, Feb. 21, 1949.

Rubella Teamwork in Holland

Shortly after the war, in a scientific meeting sponsored by the *Nederlandsch Tijdschrift voor Geneeskunde*, Professor van Gilse, otologist in the University of Leyden, spoke about rubella and congenital anomalies.

During the war foreign literature was extremely rare in Holland, so that it was not until after the liberation that a copy of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION containing an article by Albaugh (Nov. 10, 1945, p. 719) brought insight into the combination of anomalies of a patient seen by the ophthalmologist Professor van der Hoeve and Professor van Gilse: cataract of the lens in one eye, pigment anomalies in the retina of the other eye, total deafness, anomaly of the heart and mental deficiency.

Soon after this first experience and well informed meanwhile by the literature that had appeared since the first publications of Gregg (1941, 1942) a working group started studying the problem in the Netherlands. Many data were collected by the inquiries of Miss E. Kamerbeek, school physician (Rotterdam), in the five Netherland institutions for the deaf and dumb and afterward among specialists all over the country.

Till now, Professor van Gilse's team has studied in Holland 124 cases of congenital anomalies in children whose mothers suffered from a rubella infection during the first months of pregnancy; 52 patients were registered by ophthalmologists (41 of them were operated on for cataract by Professor Weve, Utrecht), and 34 were found in the schools for deaf and dumb.

The team gave attention to the many sides of the problem. The virus work was done under the auspices of the Institute of Preventive Medicine at Leyden (Prof. J. P. Bijl and Prof. J. D. Verlinde). Attempts to obtain the virus have not been successful, and the infection of monkeys also failed.

Hildernisse and Verlinde without success repeated the work of Steinmaurer (Vienna), who believes that he has followed the development of the virus in the body by means of the electron microscope. They confirmed the specific phenomenon of the intracutaneous injection of convalescent serum during the incubation period: no exanthem occurred on the spot of the injection.

In accordance with Möschlin (Zürich), great value was attached to the presence of "plasma cells" in the blood. The hematologist S. J. de Vries (Amsterdam), and also Rietra (Amsterdam), called attention to the fact that there is no common opinion on the significance of the "plasma cells" or "pathologic lymphocytes." However, the impression of the members of the research team is that one does well to give adequate importance to the results of the blood examination along with other criteria. These pathologic blood elements occur in increasing numbers during the first days after the eruption of the exanthem. In 1 case of a tonsillectomy on the day when rubella appeared, the pathologist Miss van Beek (Leyden) found a layer of plasma cells under the epithelium of the tonsils.

Administration of convalescent serum or specific globulin was stated to be the only prophylaxis today, besides promoting rubella in as many young girls as possible. In this country the induced abortion is mostly rejected for ethical-religious as well as for practical reasons: The 100 per cent anomalies in case of rubella in the first two months of pregnancy are not as absolutely certain as was stated in the first Australian publications. One does not know to what extent the anomalies will appear. Cataract may be operated on with success. For deaf children possibilities exist of making suffering bearable.

Attempts to infect adults in order to obtain serum have failed. On the other hand, the State Institute, the Central Blood Transfusion Service of the Red Cross, the Health Services of Amsterdam and Rotterdam and many provincial centers are cooperating in the gathering of convalescent serum. Appeals to the general practitioners are also regularly made in the medical periodicals. In all the cases of pregnant women who in the first months had been likely to be infected with rubella and had been given injections during the supposed incubation period, the disease did not appear; the children born were healthy. Cases in which the convalescent serum was given in the beginning of the disease have not been recorded.

ITALY

(From Our Regular Correspondent)

FLORENCE, Jan. 25, 1949.

National Surgical Association

The fiftieth Congress of the Italian National Surgical Association was held in Bologna last October, contemporaneously with the Congress of Internal Medicine. The first subject, "Visceral Pain," was reported on in a previous letter. The second subject was "Surgery of the Vagus." The speaker, Professor Pieri, Rome, discussed the clinical indications of vagotomy based on observations in 151 patients operated on; vagotomy was performed on 142 patients and resection of the branches of the vagus on 9 patients. Good results were obtained with vagotomy in neuralgia of the vagus, in bronchial asthma and in gastric neurosis. Tuberculous laryngitis provided good indications for resection of the superior laryngeal nerve, but this method is now surpassed by the treatment with streptomycin and aerosols. Results were not satisfactory in toxic diffuse goiter, cardiospasm and cancer of the esophagus.

In 1927 Professor Pieri suggested vagotomy as a method of treatment for peptic ulcer, a suggestion based on the belief that the process of autodigestion of the gastric mucosa may result from a functional lack of equilibrium of the innervation of the stomach, with the vagal effects prevailing. This method, however, was not practiced at this time; it was only in 1943, after the reintroduction by Dragstedt, that vagotomy was practiced on a large scale. In 130 cases of vagotomy, on which the speaker's experience is based, results always were fairly satisfactory, although it has not yet been possible to pass final judgment. Today one can state that vagotomy is indicated in recurrences of peptic ulcer, in high gastric ulcers and in duodenal ulcers. Vagotomy, as a rule, should be combined with gastroenterostomy. Concerning the technic the speaker favors subdiaphragmatic vagotomy for gastric neuroses and peptic ulcers. The mortality rate is 3.3 per cent.

Those who participated in the discussion which followed the report were in favor of vagotomy when it is indicated. Professor Dogliotti, of the University of Turin, was in favor of subdiaphragmatic vagotomy for gastroduodenal ulcers, on the basis of his own 70 cases. He suggested calling vagotomy "Pieri's operation" in honor of the surgeon who first conceived and applied it.

The third subject of the Congress was "Postoperative Tetanus." The speaker, Professor Giovannini from Bologna, started from the premise that, notwithstanding the most careful asepsis before and during surgical intervention, there may still be observed cases of postoperative tetanus; i. e., those which occur after surgical intervention carried out with due precautions in an area which has not been infected with Clostridium tetani during recent trauma. The pathogenesis constitutes the central problem of the question. The exogenic origin of tetanus was demonstrated in some cases (use of contaminated material or improperly sterilized instruments). The part which surgical gut may play in the occurrence of tetanus in these cases has been exaggerated. The preoperative iodinization, however, of the surgical gut according to suitable standards is a satisfactory prophylactic safeguard against the tetanus germ.

One must admit that in many cases the tetanus is of endogenous origin. The surgical intervention provides for the germ, a saprophyte already present in the organism, the optimum local and general conditions under which it may develop. In a few cases one may admit that tetanus has been present before the intervention and that it was manifested clinically only after the intervention.

Specific prophylaxis consists of simultaneous injections of serum and anatoxin in different areas; these should be repeated conveniently. The most rational treatment consists of serum-anatoxin therapy by any route according to the preference of the individual surgeon. Curare is a useful sedative for the muscles. Penicillin is effective. The mortality from postoperative tetanus still varies from 50 to 70 per cent.

The fourth subject on which reports were made was "Anesthesia by Endotracheal Intubation" and "Curare in Anesthesia." The subject was divided in two parts. The first part ("Endotracheal Anesthesia") was presented by Dr. Cura and Dr. Manzocchi from Milan, who affirmed that the adoption of the endotracheal technic in the field of inhalation narcosis constitutes the realization of one of the most important advances in the realm of anesthesia.

One speaks of endotracheal anesthesia by means of insufflation when the anesthetic mixture is introduced into the lungs under positive pressure; on the contrary one speaks of endotracheal anesthesia by means of inhalation when the anesthetic mixture is inhaled and exhaled by means of an endotracheal catheter with atmospheric pressure; the latter today is the technic almost universally adopted.

After a description of the instrumentarium (Magill's tube, laryngoscope, Magill's forceps, nebulizer) the speakers discussed the technic of intubation of the trachea; they emphasized that it should be carried out rapidly and without trauma. Muscular relaxation and absence of reflexes are essential for preventing complications. If one wants to follow the orotracheal route the position of the patient represents the most important technical detail; Chevalier Jackson's second position should be preferred. If one wants to follow the rhinotracheal route, tubular breathing is to be considered the safest guide on the progress of the tube toward the vocal glottis; it increases as it gets nearer to the glottis and it remains as such when the tube is inside the trachea. Trauma must be avoided during the removal of the tube, and it seems convenient to perform extubation with the patient under anesthesia.

Concerning the methods of anesthesia under which intubation may be carried out, the speakers stated that after appropriate preanesthesia intubation may be performed with patient under general or local anesthesia. The speakers then listed many advantages of the endotracheal method as compared with other methods of anesthesia by inhalation, and they also mentioned a few disadvantages.

The second part of the reports was devoted to "Curare in Anesthesia." Professor Tosatti from Rome presented the history of the pharmacology of curare, and in addition its effect on man and its employment for the practice of anesthesia.

Correspondence

THE TOWN MEETING DISCUSSION OF COMPULSORY SICKNESS INSURANCE

To the Editor:—If the public had any impression that Mr. Ewing and the proponents of compulsory sickness insurance are waging a clean fight based on sound fact, the recent debate at the Town Meeting of the Air, in Town Hall, New York, should dispel such naive thinking. The attack is now concentrated on the profession of America as represented by the American Medical Association and the 85 per cent of American physicians who are determined to save the American people from the catastrophe of federalized control of the private practice of medicine.

The Utopian promises are made of free medicine (of course of the highest order!), plenty of doctors, plenty of nurses, hospitals and equipment, accelerated research in a dreamland free from disease, human error and suffering, all for 75 cents a week per person. The American Medical Association was charged with hiding behind an "Iron Curtain" through which the public may not penetrate and behind which its members cannot be heard.

A carefully planned trick of planting a question based on the protest of 136 uninformed members of the American Medical Association was used to permit Mr. Cruikshank of the American Federation of Labor to charge that the doctors are held behind this "Iron Curtain" to prevent them from supporting compulsory sickness insurance. Mr. Ewing and Mr. Cruikshank do not seem to know that the House of Delegates is made up of freely elected delegates from the state societies. All the freedom of a true democracy is the fundamental right of every member of the American Medical Association. Any charge to the contrary springs from ignorance of the functions and operations of our House of Delegates.

It was obvious by the character of the planted questions at this forum that the intent is now to "divide and conquer." The attack is being concentrated on the responsible, elected leaders of the American Medical Association for one purpose and one purpose only. It is to cause dissension in our ranks. This has become a vicious fight. If ever the American medical profession needed solidarity it is now. Forget petty differences and let us show the people that we are fighting to protect them from all the evils of political medicine. Let us not be drawn into the trap being set by those who would capitalize on the defections of a few.

F. F. Borzell, M.D.,
Speaker of the House of Delegates, Philadelphia.

PHYSICIANS FOR THE ARMED FORCES

To the Editor:—In regard to your Current Comment headed "Drive To Obtain Physicians For The Armed Forces Recommended," in The Journal, February 12, I should like to offer the following suggestions:

1. Service should be compulsory in the armed forces for all A.S.T.P. and Navy V-12 students who secured their medical education at government expense and who for various reasons were discharged from the services when their medical education was completed; they should now be made to give the two year period that other men who were not discharged have been giving.

2. Those men of military age (to 60 years) who did not serve in the armed forces in World War II by reason of "essentiality" or physical reasons, dependents (the United States considers an army officer's pay sufficient to keep a family) or who were able to ignore the war and go about their own interests, should be inducted and "allowed" to do their bit for two years. This class would secure the needed specialist care that the armed forces lack.

It should be borne in mind that a man up to the age of 60 who is able to practice in civilian life is able to serve his country in time of peace. The younger men can serve in the more active assignments, the older men in hospitals, dispensaries, recruiting, sea assignments on larger ships.

Proper regulations can readily be made that will provide physical examinations and records that will prevent those serving in these two classes from securing a retirement for disability that is not a legitimate claim from service acquired injury or illness.

If this plan should be followed there would be no shortage of physicians in the armed forces.

Robert John Carpenter, M.D.
North Adams, Mass.

REPORTS OF MEDICAL EXAMINATIONS FOR VETERANS ADMINISTRATION RATING AGENCIES

To the Editor:—The National Rehabilitation Commission of the American Legion wishes to call to the attention of the medical profession that many veterans who are attempting to get disability claims adjudicated before Veterans Administration rating agencies are experiencing delays and handicaps in accomplishment of final rating because of physicians' reports and statements which are unsatisfactory or not acceptable to the Veterans Administration for one reason or another. The purpose of this statement is to clarify what the Veterans Administration desires of physicians' reports to adjudicate claims properly. The Veterans Administration regulations require that the physician's statement be notarized only in initial establishment of service connection for a specific disease or condition. While this requirement is considered a waste of time by most physicians, it is a Veterans Administration requirement in establishing initial service connection. However, most doctors will be examining and working on reports for veterans who have already had service connection established, and are conducting the examination to determine whether the condition has improved, regressed or remained stationary. In such cases, the statement on the physician's letterhead is sufficient. Notarization is not required in these cases.

Since claims may be made months, or, in some cases, years after the physician has examined or treated the veteran for a given condition, the doctor should state in the body of his report whether the information is from his office or clinic records, or from memory. Since Veterans Administration adjudication personnel have among their number physicians, or they can obtain the advice of Veterans Administration doctors, the reports should be in professional language with no attempt to simplify the terminology for lay interpretation. Interpretation of the validity of the doctor's data in relation to the veteran's claim will be made by medical personnel. Therefore the reports should be as complete and detailed as possible.

In the report, the date of first treatment and the length of time the veteran has been observed by the doctor should be included. Details of the pertinent history and physical examination are essential. The detailed medical findings, both physical and laboratory, should be included. For instance, degree of extension or flexion of an ankle may be very important in determining adjudication results. Such detailed medical findings should be listed by the reporting physician. When this is done, the final diagnosis made by the doctor can be interpreted in the light of the data that led to the making of the diagnosis. It is not sufficient merely to state that the veteran was treated for a given condition, without giving some of the pertinent facts relative to the condition in the particular veteran. If laboratory tests or roentgenologic or other special examinations are done, reports of these should be included, if such reports are available. Some of these data may be valuable to aid the Veterans Administration in establishing the merit of a veteran's claim.

In summary, the medical report for the veteran for adjudication purposes should be complete and as detailed as possible. History, physical examination, laboratory and special examinations, with dates of period of observation and performance of examinations, are desired. Only with such complete reports can justice to the claim of the veteran be done by the Veterans Administration adjudication agencies.

T. O. Kraabel,
Director, National Rehabilitation Commission, The American Legion, Washington, D. C.

Medical Motion Pictures

FILM REVIEWS

Indirect Inguinal Hernia. 16 mm., black and white, silent (2 reels). Prepared in 1929 and produced in collaboration with the American College of Surgeons and Daniel L. Borden, M.D., Washington, D. C. Procurable on rental or purchase from Encyclopaedia Britannica Films, Inc., 1150 Wilmette Avenue, Wilmette, Ill.

Reel I, **Surgical Anatomy,** 391 feet, showing time sixteen minutes.

By animation and dissection on a cadaver some of the factors involved in the production of an indirect inguinal hernia and the anatomy encountered in performing an indirect inguinal herniotomy are illustrated. The dissection is unusually good and the structures encountered are well pointed out and captioned.

Reel II, **Clinical Aspects,** 280 feet, showing time eleven minutes.

This reel deals with the diagnosis of an indirect inguinal hernia. By means of animation superimposed on a patient, the pathologic processes sometimes present in a hernia are well depicted. Complete, incomplete, reducible, nonreducible and strangulated hernias are all illustrated.

Although these motion pictures were produced some time ago, they are basic type films and can be recommended for use in teaching residents, interns and especially medical students. They would be very valuable as an adjunct to lectures on the subject of hernias as well as surgical anatomy and anatomy.

In both reels, the animation is simple and well done and the photography is clear. From a production point of view, these films are superior in some respects to many which have been produced in more recent years.

Curare in Barbiturate Oxygen Anesthesia. 16 mm., color, sound, 700 feet (1 reel), showing time nineteen minutes. Prepared by T. C. Davison, M.D., and A. H. Letton, M.D., Atlanta, Ga. Produced in 1948 and procurable on loan from E. R. Squibb & Sons, Motion Picture Department, 745 Fifth Avenue, New York 22.

This film presents mainly the way patients are handled at the Georgia Baptist Hospital and demonstrates that more relaxation can be secured and intravenous administration of less thiopental sodium required, if both thiopental and curare are administered. It illustrates a vagotomy with patient under thiopental-oxygen-intocostrin® anesthesia. Several other surgical procedures under the same anesthetic management are briefly shown. More emphasis is placed on the surgical and general hospital care of patients than on detailed information pertaining to the anesthetic management.

The statistical material presented by the narrator dealing with the advantages of thiopental-oxygen-curare mixtures over thiopental-oxygen alone would have been clearer and more concise if given in table form. Since these drugs do not have truly analgesic properties, and both thiopental and intocostrin® have potentially great and not always predictable depressant action as regards respiration, there should be a demonstration by the responsible physicians of the diagnosis and management of the physiologic changes produced by such drugs. More discussion of the treatment of overdosage is needed, as well as enumeration of, and means of avoiding, the various complications that may occur during or following either intravenous administration of thiopental or administration of curare.

In the introductory part of this motion picture, there is a considerable amount of unnecessary footage which shows in great detail a patient leaving her car walking up the steps to the entrance of the hospital, routine of admission and medical examination for a peptic ulcer followed by the surgical operation and her convalescence period. A greater part of this should have been deleted and the opening scene replaced by showing the operating room and patient ready for surgery.

The photography is excellent. However, from a production standpoint the film is very poorly done.

Thyroidectomy by Electro-Surgery. 16 mm., color, silent, 787 feet (2 reels), showing time thirty minutes. Prepared in 1941 by and procurable on loan from Arnold S. Jackson, M.D., Jackson Clinic, Madison, Wis.

This film is designed to show the preoperative procedure, the operative technic of a thyroidectomy and postoperative care at the Jackson Clinic. It demonstrates a skilful method of excising most of the thyroid gland by the use of the electrocautery. This method necessitates local anesthesia, which in turn demands heavier preoperative medication, longer incisions, wider exposure, less pulling on retractors and much more gentleness. The large vessels must be recognized and tied separately by ligature. Hemostasis must be completed by suturing the capsular edges of the remnant; to do this the remnant should be hollowed out to form a concave surface. All these technics are necessary to accompany the electrocautery method.

The second reel is more or less a repetition of the first reel. The diagnostic tests portrayed are of little value to one sufficiently informed to appreciate the technic.

The technic and surgical anatomy are not sufficiently detailed to be of much use to the uninitiated but are of value and interest to a surgeon already familiar with surgery of goiter.

The film was made before the advent of thiouracil derivatives. The short discussion on preoperative treatment, evaluation of risk and two stage operations is antiquated but because of its brevity does not detract from the film.

The photography of the patients is only fair; however, the surgical sequences are excellent.

Supradiaphragmatic Gastric Vagotomy for Peptic Ulcer, the Abdominal Approach. 16 mm., color, silent, 550 feet (2 reels), showing time twenty minutes. Prepared in 1948 by Lester R. Dragstedt, M.D., Ph.D., Chairman, Department of Surgery, University of Chicago. Procurable on loan from Davis & Geck, Inc., 57 Willoughby Street, Brooklyn 1.

Reel I: A series of drawings illustrates the technic of the operation and the anatomy of the vagus nerves at the lower end of the esophagus and at the upper part of the stomach.

Reel II presents an excellent demonstration of the technic of transabdominal vagotomy as performed by the author.

Although the operation is done on a patient who has a duodenal ulcer without obstruction, the ulcer is not demonstrated sufficiently well for one to note its size or position and whether it is causing obstruction. The operative procedure is illustrated by a series of drawings. An upper left rectus incision is made. The triangular ligament is divided enabling mesial retraction of the left lobe of the liver. The mediastinum is opened and traction is placed on the esophagus to bring it into the abdomen for a distance of about 5 cm. The vagus nerves are demonstrated and approximately 3 to 4 cm. excised. The cut ends are ligated. The incised visceral peritoneum is resutured and the mediastinum and abdominal wall closed.

The postoperative care of the patient's stomach by use of an indwelling gastric tube to which is attached a continuous suction apparatus is depicted briefly. Additional information on prevention of impending dehydration, toxemia and electrolyte imbalance, and marked loss of gastric secretion, which is sometimes prolonged for several days, would be of value.

Much footage was used in closing the incision, which seems to be a routine closure.

This motion picture is recommended for showing to general surgeons, general practitioners, residents, interns and medical students.

Photography, animation and visual demonstration are excellent with the exception of a few places in Reel II, where the surgeon's right hand obstructs the operative field. This part could well be eliminated.

Council on Medical Education and Hospitals

DISCONTINUATION OF GRANTING TEMPORARY APPROVAL TO RESIDENCY TRAINING PROGRAMS

The Council on Medical Education and Hospitals has voted not to grant any additional temporary approvals for residency training programs. This action, effective as of Jan. 1, 1949, was taken in concurrence with the Advisory Board for Medical Specialties. Hereafter, residency training programs will be considered for approval only after the programs have been inspected by representatives of the Council. The Council plans to inspect in the near future all residencies holding temporary approval as of Jan. 1, 1949. On the basis of the findings of the inspections, the Council in concurrence with the specialty boards concerned will decide whether to grant these residencies full approval or to discontinue approval.

Donald G. Anderson, M.D., Secretary.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: *Parts I and II.* Various Centers. June 20-22, Sept. 12-14. *Part II.* April 25-26. Exec. Sec., Mr. E. S. Elwood, 225 S. 15th St., Philadelphia 2.

EXAMINING BOARDS IN SPECIALTIES

American Board of Anesthesiology, Inc. *Written.* Various Centers. July 15: Final date for filing application is April 15. *Oral.* April 10-14 and Oct. 16-20. Sec., Dr. Curtiss B. Hickcox, 745 Fifth Ave., New York 27.

American Board of Dermatology and Syphilology: *Oral.* New York City, April 1-3. Sec., Dr. George M. Lewis, 66 East 66th Street, New York 21.

American Board of Internal Medicine: *Oral.* New York City, March 23-25. Philadelphia, June 1-3. *Written.* Oct. 17. Final date for filing application is May 1. Asst. Sec.-Treas., Dr. W. A. Werrell, 1 Main St., Madison 3, Wis.

American Board of Neurological Surgery: *Oral.* Chicago, June 1949. Sec., Dr. W. J. German, 310 Cedar Street, New Haven, Conn.

American Board of Obstetrics and Gynecology, Inc.: *Oral.* Chicago, May 8-14. Final date for filing application is April 1. Sec., Dr. Paul Titus, 1015 Highland Building, Pittsburgh 6.

American Board of Ophthalmology: *Oral.* San Francisco, March 21-24; New York, June 11-15; St. Louis, Oct. 15-19; Boston Dec. Sec., Dr. S. J. Beach, 56 Ivie Rd., Cape Cottage, Maine.

American Board of Orthopaedic Surgery. *Part I.* New York City, April 22-23; Atlanta, Ga., April 29-30; Indianapolis, May 6-7 and Denver, May 13-14. *Part II.* New York City, Jan. 1950. Final date for filing application for Part II is Aug. 15. Address: Dr. Francis M. McKeever, 1136 W. 6th St., Los Angeles 14, Calif.

American Board of Otolaryngology: New York, May 11-14. *Chicago, Oct. 4-7. Sec., Dr. D. M. Lierle, University Hospital, Iowa City.*

American Board of Pathology: Boston, April 12-13. Sec., Dr. Robert A. Moore, 507 S. Euclid Ave., St. Louis 10, Mo.

American Board of Pediatrics: *Oral.* Baltimore, May 7-9. Exec. Sec., Dr. John McK. Mitchell, 6 Cushman Rd., Rosemont, Pa.

American Board of Physical Medicine. Atlantic City, June 4-5. Sec., Dr. R. L. Bennett, 30 N. Michigan Blvd., Chicago.

American Board of Plastic Surgery: Examinations are given in June and November of each year in the home town of applicants. Sec., Treas., Dr. Louis T. Byars, 400 Metropolitan Bldg., St. Louis, Mo.

American Board of Psychiatry and Neurology, Inc. December, New York City. Sec., Dr. F. J. Braceland, 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Radiology. Atlantic City, June 2-4. Sec., Dr. [illegible] Second Ave., S.W., Rochester, Minn.

[illegible] gery: *Written.* Various Centers, October. Fi[illegible]on is July 1. Sec., Dr. J. Stewart Rodman, 22[illegible]

American Board of Urology: Feb. 1950. Sec., Dr. Harry Culver, 7935 Sunnyside Road, Minneapolis 18, Minn.

BOARDS OF MEDICAL EXAMINERS

Alabama: *Examination.* Montgomery, June 28-30. Sec., Dr. D. G. Gill, 519 Dexter Ave., Montgomery.

Arkansas:* Little Rock, June 9-10. Sec., Dr. L. J. Kosminsky, Texarkana. *Eclectic.* Little Rock, June 9-10. Sec., Dr. C. H. Young, *1415 Main St., Little Rock.*

[illegible]: *Examination.* San Francisco, June 20-23. Sec., Dr. Fr[illegible] St., Sacramento. [illegible] Denver., April 5. *Written*, Denver, June 20-22. Sec., Dr. W. W. King, 831 Republic Bldg., Denver 2.

Delaware: Dover, July 12-14. Sec., Dr. J. S. McDaniel, 229 South State St., Dover.

District of Columbia: * *Written*, Washington, May 9-10. Sec., Dr. George C. Ruhland, 4130 Municipal Bldg., Washington.

Florida: * *Examination*, Jacksonville, June 26-28. Sec., Dr. Frank D. Gray, 12 N. Rosalind Ave., Orlando.

Georgia: *Examination.* June, Atlanta and Augusta. *Reciprocity.* Atlanta. June. Sec., Mr R. C. Coleman, 111 State Capitol, Atlanta.

Guam: *Endorsement.* Agana, Last Friday of each month. Sec., Capt. C. K. Youngkin, Dept. of Public Health, Guam. % F.P.O., San Francisco, Calif

Hawaii: * *Examination.* Honolulu, July 11-14. Sec., Dr. S. E. Doolittle, 881 S. Hotel St., Honolulu.

Idaho: Boise, July 11-13. Sec., Miss Estella S. Mulliner, Bureau of *Occupational Licenses, 355 State House, Boise.*

Illinois: Chicago, April 12-14. Supt. of Registration, Mr. Fred W. Ruegg, Capitol Bldg., Springfield.

[illegible]: [illegible] I[illegible]napolis, June 21-23. Sec. Board of Medi[illegible] Dr. Paul R. Tindall, *416* K. of P. Bldg., [illegible]

Iowa: * *Examination.* Iowa City, June 13-15. Sec., Dr. M. A. Royal, 506 Fleming Bldg., Des Moines.

Kansas: Kansas City, June 1-2. Sec., J. F. Hassig, 905 North 7th St., Kansas City, Kans.

Kentucky: *Examination.* Louisville, June 15-17. Sec., Dr. Bruce Underwood, *620 S. 3rd St.*, Louisville 2.

Maryland: *Examination.* Baltimore, June 21-24. Sec., Dr. Lewis P. Gundry, 1215 Cathedral St., Baltimore. *Homeopathic.* Baltimore, June 14-15. Sec., *Dr.* John A. Evans, 612 West 40th St., Baltimore.

Minnesota: * Minneapolis, April 19-21. Sec., *Dr. J. F.* Du Bois, 230 Lowry Medical Arts Bldg., St. Paul 2.

Mississippi: Jackson, June 21-22. Asst. Sec., Dr. R. N. Whitfield, State Board of Health, Jackson.

Missouri: *Examination.* St. Louis, May 30-31 and June 8-10. Exec. Sec., Mr. John A. Hailey, Box 4, Jefferson City.

Montana: Helena, April 4-6. Sec., Dr. O. G. Klein, First National Bank Building, Helena

Nebraska: * *Examination.* Omaha, *June. Dir., Bureau* of Examining *Boards*, Mr. Oscar F. Humble, 1009 State Capitol Building, Lincoln 9.

Nevada: Carson City, May 2. Sec., Dr. G. H. Ross, 112 N. Curry Street, Carson City.

New Jersey: *Examination.* Trenton, June 21-24. Sec., Dr. E. H. Hallinger, 28 West State Street, Trenton 8.

New Mexico: * Santa Fe, April 11-12. Sec., Dr. V. E. Berchtold, 141 Palace Ave., Santa Fe

New York: Albany, Buffalo, New York and Syracue, June 28-July 1, Sec., Dr. Jacob L. Lochner, *23* South Pearl St., Albany.

North Carolina: *Endorsement.* Pinehurst, May 9. *Examination. Raleigh, June 23-25.* Sec., Dr. Ivan Procter, 226 Hillsboro St., Raleigh.

Ohio: *Endorsement.* Columbus, April 5 *Written.* Columbus, June. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.

Oregon: * *Endorsement.* Portland, April 29-30. *Examination.* Portland, July. Exec. Sec., Mr. Howard I. Bobbitt, 609 Failing Bldg., Portland.

Pennsylvania: *Examination.* Philadelphia and Pittsburgh, July. Acting Sec., Mrs. B. G. Steiner, 351 Education Bldg., Harrisburg.

Rhode Island: * *Examination.* Providence, April 7-8. Chief, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

South Carolina: *Examination.* Columbia, *June 27-29.* *Endorsement.* Columbia, March 7, April 4, May 2, June *27-28*, Aug. 1, Sept. 5 and Oct. 3. Sec., Dr. N. B. Heyward, 1329 Blanding St., Columbia.

South Dakota: * *Examination.* Pierre, July 19. Sec., Dr. G. J. Van Heuvelen, Capitol Bldg., Pierre.

Tennessee: * *Examination.* Memphis, March 23-24. Sec., Dr. H. W. Qualls, 1635 Exchange Bldg., Memphis.

Texas: *Examination.* Austin, June 16-18. Sec., Dr. M. H. Crabb. 209 Medical Arts Bldg., Fort Worth 2.

Utah: *Examination* Salt Lake City, July. Sec., Dept. of Registration. Miss Rena B. Loomis, 324 State Capitol Bldg., Salt Lake City.

Virginia: *Examination.* Richmond, June 17-18. *Reciprocity.* Richmond. June 16. Dr. K. D. Graves, 631 First St., S.W., Roanoke.

Washington: * Seattle, July. Sec., Mr. Edward C. Dohm, Department of Licenses, Olympia.

West Virginia: Charleston, April 7-9. Sec., Dr. N. H. Dyer, State Capitol, Charleston 5.

Wisconsin: * *Examination.* Milwaukee, June 28-30. Sec., Dr. C. A. Dawson, Tremont Bldg., River Falls.

Wyoming: Cheyenne, June 6. Sec., Dr. Franklin D. Yoder, Capitol Bldg., Cheyenne.

* Basic Science Certificate required.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Arkansas: *Examination.* Little Rock, May 3. Sec., Mr. L. E. Gebauer, 1002 Donaghey Bldg., Little Rock.

Colorado: *Examination.* Denver, June 1-2. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver.

District of Columbia: *Examination.* Washington, April 18-19. Sec., Dr. George C. Ruhland, 4130 Municipal Bldg., Washington.

Florida. *Examination.* Gainesville, June 11. Sec., Mr. M. W. Emmel, University of Florida, Gainesville.

Iowa: *Examination.* Des Moines, April 12. Sec., Dr. Ben H. Peterson, Coe College, Cedar Rapids.

Michigan: *Examination.* Detroit and Ann Arbor, May 13-14. Sec., Miss Eloise LeBeau, 101 N. Walnut St., Lansing 15.

Minnesota: *Examination.* April 4, June and Oct. Sec.-Treas., Dr. Raymond N. Bieter, 105 Millard Hall, Univ. of Minnesota, Minneapolis.

New Mexico: *Examination.* Santa Fe, March 20. Sec., Miss Marguerite Kilkenny, 110 W. Houghton St., Santa Fe.

Oklahoma: April 15. Sec., Dr. Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

Oregon: Portland, June 18, *Sept. 3 and Dec. 3.** Sec., Mr. Charles D. Byrne, State Board of Higher Education, Eugene.

South Dakota: Vermillion, June 3-4. Dr. G. M. Evans, 310 E. 15th St., Yankton.

Tennessee: Memphis, March *21-22* and July 8-9. Sec., Dr. O. W. *Hyman, 874* Union Ave., Memphis 3.

Wisconsin: Madison, April 2. Milwaukee, June 4. Sec., Prof. W. H. Barber. Ripon College, Ripon.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1938 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Journal of Public Health, New York

38:1361-1498 (Oct.) 1948. Partial Index

*Recent Developments in Treatment of Syphilis. E. W. Thomas. —p. 1361.
Some Unmet Needs in Tuberculosis Control—Challenge for the Future. W. P. Shepard.—p. 1370.

Coordination of Preventive and Curative Services in Maryland. W. H. F. Warthen.—p. 1393.
Comparison of Immunogenic and Anaphylactogenic Properties of Rocky Mountain Spotted Fever Vaccines Prepared from Infected Yolk Sacs and from Infected Tick Tissue. D. Lackman and R. R. Parker. —1402.
Laboratory Procedure for Evaluating Practical Performance of Quaternary Ammonium and Other Germicides Proposed for Sanitizing Food Utensils. G. R. Weber and L. A. Black.—p. 1405.
Abortion as Cause of Death. C. Tietze.—p. 1434.
Epidemiologic Approach to Accident Prevention. E. Press.—p. 1442.

Treatment of Syphilis.—Thomas evaluated the present status of penicillin in the treatment of syphilis. The time-dose relationships of therapy with aqueous solutions of penicillin are different from those with slowly absorbed preparations. So far, the best results in the treatment of early syphilis seem to have been obtained with daily injections of 300,000 to 600,000 units of penicillin in oil and beeswax for fifteen days. Procaine penicillin G in oil and 2 per cent aluminum monostearate can now be substituted for penicillin in oil and beeswax, and individual injections of this preparation do not have to be given as frequently as with penicillin in oil and beeswax. Probably two injections of 600,000 units of this preparation a week for two or three weeks will accomplish as much as daily injections of 300,000 units of penicillin in oil and beeswax for fifteen days. Neurosyphilis should be treated with at least 6,000,000 units of penicillin over a period of not less than fifteen days and preferably three weeks. Injections of 600,000 units of procaine penicillin in oil and aluminum monostearate three times a week for three weeks should prove sufficient therapy for most cases of neurosyphilis. For late symptomatic and late latent syphilis from 4,000,000 to 6,000,000 units of penicillin should be given over a period of not less than fifteen days. In most cases of late syphilis, whether symptomatic or asymptomatic, it is impossible to reverse positive serologic reactions for syphilis to negative within five or more years. Such patients should be observed with quantitative serologic tests at regular intervals. Great rises in quantitative tests from previous levels, sustained for several weeks or months, are an indication for further therapy.

Reflex Sympathetic Dystrophy (Causalgia of Extremities).—Toumey defines reflex sympathetic dystrophy as a disturbance of the sympathetic nervous system, characterized by pain and sympathetic phenomena which may follow traumas. There has been an enormous confusion of terms; the following terms were used in describing the 31 cases reviewed here: "reflex sympathetic dystrophy," "causalgia," "minor causalgia," "post-traumatic pain," "traumatic sciatica," "post-traumatic sympathetic phenomena," "Sudeck's atrophy" and "nerve injury." The diagnosis of reflex sympathetic dystrophy rests on the clinical picture of sympathetic phenomena, which include: coldness, changes in skin color, increased sweating, swelling and atrophy of skin and bone, plus the relief of pain, sweating and coldness by procaine sympathetic blocks. Sympathectomy is justified if good, but not permanent, results are obtained by the procaine sympathetic blocks. Sympathectomy was performed at the Lahey Clinic in the cases reviewed in this paper. It relieved pain in two thirds of the 31 cases. Surgery, such as arthrodeses of painful joints, may be required in addition to sympathectomy. The best results were achieved in patients who had had reflex sympathetic dystrophy for relatively short periods and in those who were in the younger age groups. If the result of the block is poor, the result of the sympathectomy will also be poor, but even though the result of the block is good, the result of sympathectomy will not be good in all cases. The prevention of reflex sympathetic dystrophy depends on treating traumas so that pain is minimized and function is restored to the extremity as rapidly as possible.

Estrogens and Bone Formation.—Sherman shows that in the human female estrogens are in some fashion concerned with the rate of growth and maturation of the skeleton. Investigators have studied postmenopausal osteoporosis as a hormonal deficiency and have found that they could produce and maintain calcium retention in the human being by the injection of estrogens. However, these workers admit that irrefutable evidence that the bones have actually become more dense has never been obtained by them. The author presents the history of a patient in whom this was possible. The patient, a woman, aged 58, had had a surgical menopauseventeen years before, but the diagnosis of postmenopausal osteoporosis could not explain the greatly elevated phosphatase level or the roentgenographic appearance of the skull. Moreover, it is hard to conceive of a generalized process which would spare one tibia while the other practically disappeared, without involvement of the fibula, and affect the lumbar spine and pelvis so severely, while the rest of the trunk remained relatively normal. It was concluded that the picture could best be interpreted as a severe postmenopausal osteoporosis, superimposed on previously existing Paget's disease. Massive estrogen therapy was followed by a remission of clinical symptoms and by actual reconstitution of bone. Withdrawal of the estrogen produced an exacerbation; its readministration was again followed by improvement. For over two years the patient has been kept on daily doses of 2,000 to 10,000 rat units (0.33 to 1.66 mg.) of estradiol benzoate; during this time she has maintained her improvement and has not shown untoward symptoms.

Streptomycin in Chronic Infections of Bone.—The purpose of the study conducted by Wilson was to determine whether or not the systemic and local use of streptomycin, in addition to thorough sequestrectomy and painstaking care of the wound, would hasten the healing of wounds in patients ill with osteomyelitis of long duration. Twenty-five cases of chronic osteomyelitis are reported in which discharging sinuses had been present for an average of nineteen months. Many types of treatment had been tried, without success. A plan of therapy was evolved on the following principles: (1) thorough investigation of the wound bacteria; (2) radical sequestrectomy after adequate preoperative preparation; (3) the use of streptomycin and penicillin before, during and after surgery; (4) painstaking care of the wound after surgery to prevent contamination. Twenty-one patients have responded favorably, but 4 patients failed to respond and have had amputation. The author emphasizes that the use of streptomycin offers no panacea for the treatment of chronic osteomyelitis. The drug cannot replace adequate surgery, but, when combined with thorough sequestrectomy, it is beneficial.

Rickettsialpox.—According to Rose rickettsialpox is a disease entity which was first recognized in 1946 and has not been observed outside New York city. Huebner and others identified the causative agent as Rickettsia akari and showed that the infection is, in all likelihood, transmitted to man by the bite of a rodent mite, Allodermanyssus sanguineus. These investigators isolated R. akari from mice trapped in apartment houses when cases of rickettsialpox had occurred. Rickettsialpox is now common in New York city. More than 350 cases have been reported to the department of health since the spring of 1946. The author reports 3 cases which illustrate important features of the disease and reviews observations on 17 patients who were hospitalized for rickettsialpox. In 15 of the 17 patients a primary lesion could be identified with certainty. These consisted of areas of erythema and induration from 1.0 to 2.5 cm. in diameter. The rash usually appeared within six days after the onset of fever. The constitutional symptoms were fever, headache, chills and backache or general muscular aching. These symptoms appeared from two to seven days after the appearance of the primary lesion. The fever curve was of the remittent type and fell to normal by lysis, generally within a week. Headache was a prominent feature and was usually frontal. Attempts were made in 9 patients to recover the causative agent by inoculating blood collected early in the disease into mice, guinea pigs and chick embryos. R. akari was successfully isolated from 7 of the patients by mouse inoculation, and from 1 of these patients the organism was also cultivated directly in chick embryos. Rickettsialpox is a nonfatal disease and only symptomatic measures are required. A laboratory infection with rickettsialpox was not modified by streptomycin.

Diet Studies in Pregnancies.—Dieckmann and his associates show that reports of the value of an adequate amount of the proper foods in pregnancy show major inconsistencies. In a preliminary study of 100 patients the protein intake of most of the women was found to be below 85 Gm. per day. In some cases, instruction to increase the protein intake resulted in only small changes in food intake. In other cases, improvements were made. A preliminary study of the data demonstrates the value of weighing the food intake and periodically determining the protein balance. Studies on nutrition in pregnancy are being carried out in several other institutions. It is hoped that the results can be pooled and definite conclusions, based on an adequate number of patients, can be made as to what foods the pregnant woman should eat.

Cardiac Catheterization.—This report by Burchell and his associates is based on 60 cardiac catheterizations on patients who presented problems in diagnosis. The method provides information as to (1) the parts of the heart, intrathoracic veins or great vessels that may be entered by the catheter and recognized roentgenoscopically, (2) the oxygen content of the blood from the parts catheterized and (3) the pressure in the chambers or vessels that have been catheterized. A fourth feature, the recording of intraventricular electrocardiograms, will eventually be incorporated into the routine catheterization procedure. Complete failure of the catheter to enter the thoracic cavity occurred once. In this patient the superior vena cava was apparently anomalous or obstructed. Partial failure, such as inability to get into the pulmonary artery, even when pulmonary stenosis was considered not to be present, or the inferior vena cava or the right ventricle, has been experienced in as high as 25 per cent of the patients with congenital cardiac lesions. The authors have found cardiac catheterization in congenital cardiac disease particularly helpful in (1) the differentiation of Eisenmenger's complex from pulmonary stenosis (tetralogy of Fallot), (2) the recognition of atrial and ventricular septal defects when the diagnosis was in doubt clinically, (3) the investigation for a patent ductus arteriosus when a typical murmur was absent and (4) the diagnosis of essential pulmonary hypertension. In patients with tetralogy of Fallot, the authors regard catheterization only occasionally indicated for diagnosis, because of expected difficulties in catheterization and because they have considerable confidence in the oximetric test during exercise. Catheterization is of value in any condition that may simulate congenital heart disease, such as essential pulmonary hypertension. It has a wide field of usefulness as a method to be utilized for clinical investigation, particularly when information on cardiac output in a steady physiologic state is wished.

Diagnosis of Acute Poliomyelitis.—Kehoe shows that poliomyelitis may present difficulties in diagnosis. Among 100 patients admitted to a hospital for crippled children with a presumptive diagnosis of poliomyelitis, the diagnosis was established in 77, whereas the other 23 were subsequently proved to have other diseases. There is no single pathognomonic element of history, symptom, sign, physical or laboratory observations which will offer a positive diagnosis of acute anterior poliomyelitis. Accurate history, a thorough physical examination and good clinical judgment must all be combined to make the diagnosis. However, cervical rigidity, muscular weakness or paralysis, muscular soreness and loss of deep tendon reflexes in the involved areas are among the most significant findings which must be sought, together with the lesser pathognomonic findings of moderate temperature elevation, headache, irritability, nausea, vomiting and constipation. A series of symptoms found in many acute diseases but rarely in poliomyelitis is listed.

Lymphopenia of Roentgen Irradiation.—Price presents an analysis of the hematologic data collected during the treatment of a group of 16 women with 200 kilovolt roentgen rays. The observed response of the lymphocytes was characteristic in type and can be correlated with the integral dose. The major change in the total lymphocyte count takes place during the early part of a course of treatment. It may be the result of the direct action of the radiation, and the drop in the total lymphocyte count due to this is large and relatively rapid. The further drop in the total lymphocyte count which takes place in addition to this may be due to the indirect action of the radiation, which effect tends to diminish as the dose of radiation increases. Eventually, a stage is reached at which further irradiation, at the rates of dosage here considered, causes only a very small change in the total lymphocyte count.

Pulmonary Schistosomiasis.—According to Erfan pulmonary schistosomiasis occurs in the early stage of schistosomal infection, during the passage of cercaria through the lungs and in the late stage from the deposition of ova and worms. The author describes the form due to the deposition of schistosome ova and worms in the lungs. In Egypt, 60 to 70 per cent of the inhabitants are infected with schistosomiasis which is pulmonary in at least 33 per cent of these. The disease affects males more often than females and is most common in children and young adults, the highest age incidence being between 10 and 30 years. It is a disease of agricultural workers. Two forms of pulmonary schistosomiasis can be recognized, bronchopulmonary and cardiovascular. In the bronchopulmonary form the pathologic lesions are in the bronchioles and alveoli. Clinically, these manifest themselves in the form of bronchial asthma, chronic bronchitis, bronchiectasis, pulmonary emphysema and pulmonary fibrosis. In the cardiovascular form the pathologic lesions are primarily in the pulmonary arterioles and, secondarily, in the pulmonary artery and its branches and in the right ventricle. The clinical picture of this form is similar to that of primary pulmonary endarteritis or Ayerza's disease. However, cyanosis, which is the most striking feature of Ayerza's disease, is absent in pulmonary schistosomiasis, and appears only when the right ventricle has failed. Early treatment with antimony compounds is important. In cases of advanced disease with enlargement of the right ventricle, they must be used with caution, as they are toxic to the myocardium. They are definitely contraindicated when the right ventricle has failed. Heart failure is treated on ordinary lines with digitalis, venesection and mercurials.

Determination of Prothrombin Time During Treatment with Dicumarol. T. Strengers and H. H. Lindeboom.

Treatment of Gastric Ulcer with Licorice Extract.—Revers says that two years ago he first reported on the administration of succus liquiritiae (licorice extract or glycyrrhiza extract) to patients with gastric and duodenal ulcers. A paste-like consistency of the extract is obtained by mixing 100 Gm. of glycyrrhiza extract in powder form with 50 Gm. of water. The patient with ulcer takes a teaspoonful of this paste three times a day. On the assumption that it exerts an influence on the wall of the stomach, the paste is given when the stomach is empty, that is, in the morning about an hour before breakfast, about half past 11 o'clock in the morning and in the evening before going to bed. In 27 of 48 patients treated in this manner the symptoms subsided between the first and fourth days; in 10 others between the fourth and eighth days, and in 6 others somewhat later. In 5 of the 48 patients the treatment remained ineffective. Favorable results were obtained with the glycyrrhiza extract also in patients with gastritis. Edema of the face and of the extremities developed in some of the patients during treatment, and these patients often complained of severe headaches, pressure in the chest and abdominal pains. Pharmacologic studies have demonstrated the presence of a spasmolytic substance in the drug.

*Glycemia in Diabetic Coma. R. Boulin.—p. 753.

Continued Prolonged Treatment of Amebiasis. Coumel, Molinier and Pedoya.—p. 754.

*Cyclic Desquamation of Epithelium of Urinary Passage in Relationship with Menstrual Cycle. L. L. Wasserman.—p. 755.

Glycemia in Diabetic Coma.—Boulin determined the glycemia in 81 patients with diabetic coma. At the onset of the coma the sugar in the blood varied from 1.11 to 12.20 Gm., and its average was 4.59 Gm. In 2 patients the amount varied from 1.20 to 2 Gm., and in 2 additional patients it varied from 1 Gm. to 1.20 Gm. and was therefore practically normal. These latter cases of diabetic coma in the absence of hyperglycemia justify the intravenous administration of isotonic dextrose solution. This technic does not present any inconvenience with regard to diuresis. Amounts up to 596 Gm. of isotonic dextrose solution have been administered intravenously without untoward reaction. The blood sugar tends to increase in proportion to the tendency of the alkaline reserve to decrease. The amount of insulin required does not correspond to the blood sugar level at the onset of the coma. Considerable amounts of the drug may be administered safely during the first six hours after the initiation of the treatment because hypoglycemia does not occur during this period, but from then on hypoglycemia may be latent and may be manifested up to the seventy-second hour when the patient has practically recovered and no longer receives insulin except for small doses at long intervals. The blood sugar level should be determined every three hours during the period of treatment with insulin.

Desquamation of Epithelium of Urinary Passage.—Wasserman observed on examination of the urinary sediment in 30,000 cases that there is no relationship between the intensity of the desquamation of the epithelium of the urinary tract and the course of or recovery from an inflammatory process localized in the pelvis of the kidney, ureters or urinary bladder. There is little desquamation of the epithelium of the urinary tract in men. This desquamation varies considerably in women because of its relationship with the cyclic activity of the ovaries. There was little desquamation in a group of 11 girls between the ages of 1 to 7 years. In a second group of 28 girls between the ages of 9 and 15 years there was little desquamation in those who did not menstruate. Menstruation was preceded by considerable desquamation, which was restored to normal the moment that menstruation started. The menstruation was preceded likewise by a period of considerable desquamation for four to eight days in a group of 20 young women between the ages of 16 and 23 years; desquamation was restored to normal with the onset of menstruation. In a group of 10 women between the ages of 57 and 76 years the slight desquamation observed was similar to that in the girls between the ages of 1 and 7 years. In women desquamation of the epithelium of the urinary tract is diminished before the beginning of the secretory activity of the ovary and is diminished after the establishment of the menopause.

*Fuchsin in Therapy of Cholera. A. Castellani.—p. 73.

Fuchsin in Therapy of Cholera.—Castellani found that basic fuchsin kills Vibrio comma organisms without desintegrating them. It is well tolerated by men and animals and it retains its bactericidal and bacteriostatic power on V. comma even when dissolved in liquids containing pepsin and other enzymes or proteins. Basic fuchsin, in doses of 0.10 Gm. with intervals of ten minutes, up to a daily dose which varies between 1 and 2 Gm., if administered after appearance of diarrhea in cholera and preferably before appearance of vomiting, will control an attack of cholera. Basic fuchsin can be given orally in capsules or pills. The author reports a cure of all patients who had this treatment.

Substances Preventing Coagulation of Blood.—Experiments carried out by Horn and Borsodi with fresh oxalated plasma of normal persons demonstrated that the thrombokinase is capable of inactivating the heparin and occasionally the antithrombin. But only one part of the total heparin may be adsorbed or become closely attached chemically, while the other part may still be circulating in the blood in a form that may be disposed of. Additional experiments showed that toluidine blue prevents the conversion of prothrombin into thrombin. Experiments with the plasma of 11 patients with thrombosis demonstrated that in the plasma of 9 of these patients the time of the separation of the fibrin by the action of the thrombin was not shortened by the thrombokinase or by the toluidine blue, suggesting that the heparin in the form that can be disposed of may be missing in the blood of patients with thrombosis. The absence of this part of the heparin in the blood does not present the only cause of thrombosis, but it may be considered as one of the predisposing factors. Another one is the reduction of the antithrombin content of the blood, which results in a reduced capacity of the serum to dissimilate the thrombin. This capacity depends not only on the antithrombin content but also on the presence in the serum of an activating factor of enzymatic character. It is likely that the latter factor compensates for the effect of the substance which converts the thrombin. It is suggested that for the causation of thrombosis there may be necessary the concurrence of the predisposing and of other factors such as the lability of the vegetative system and the effect of temperature on the coagulation.

Book Notices

Deafness, Tinnitus, and Vertigo. By Samuel J. Kopetzky, M.D., F.A.C.S., Director of Department and Professor of Otolaryngology, New York Polyclinic Medical School and Hospital, New York. Cloth. Price, $7.50. Pp. 814, with 31 illustrations. Thomas Nelson & Sons, 385 Madison Ave., New York 17, 1948.

Any work by this distinguished otologist deserves the attention of all who are interested in the field of deafness and related subjects.

There is much which is factual in this book and a great deal which is theoretic. Thus the chapters on anatomy and physiology are not of a controversial nature and can be read with benefit to all. The essence of the author's theme is that in most cases of deafness, tinnitus and vertigo there is altered chemical composition of the blood due to a dysfunction of the enzymatic interplay. This is not presented as an entity justifying itself but as a key to purposeful therapy.

According to the author there are three types of deafness; congenital, nonprogressive and progressive deafness. He is primarily concerned with the latter type, and as regards progression of deafness makes this statement: "The prime agent in the production of the phenomenon of progressive loss of hearing is the same in all types of cases, the pertinent factor being dysfunction of the conduction and the acoustic perception mechanisms."

Biochemical studies of the blood in these latter cases show, in most, hypercalcemia and hypocalcemia, hypercholesteremia and vitamin B deficiencies. In many of the patients whose histories give evidence of vestibular disturbances there is also evidence of hypoproteinemia or hypoalbuminemia. Finally, approximately one quarter of the cases present, among other abnormalities in the chemistry of the blood, degrees of hypoglycemia.

Depending on the observations in the general physical examination, the examination of the ears and adjacent structures and the biochemistry of the blood, therapy is then predicated on specific indications. It comprises surgery when it will remove existing pathologic impedimenta to sound wave transmission to the end organ. The reader will be surprised to see that the freeing of intratympanic adhesions is more favorably considered than the fenestration operation, which receives remarkably short shrift. Jacobson's solution, histamine desensitization, diathermy and pneumomassage are recommended in selected cases, as is the currently prevalent radium therapy to the nasopharynx, and the unprevalent operation of incising the tendon of the tensor tympani muscle. When the local pathologic change is the result of systemic disease or dysfunction of the neuroglandular or endocrine system medical therapy will be required. Thus, depending on blood chemical findings, diets may be employed as in cases with an excess of urea nitrogen or uric acid, or when there is hypoglycemia. Vitamins are abundantly used, principally A for its relationship to urea clearance and hypercholesteremia and B for its effect on carbohydrate metabolism. In addition, amino acids, minerals and hormones, principally thyroid, estrogens and testosterone, are often used.

No practicing otologist could do else but joyfully welcome a physiologically based and practically successful method of therapy of these distressing conditions, for which actually little has heretofore been offered. If the author's findings are corroborated by other clinics and investigators, this may be an epochal work. But the method of approach as here presented is so new and factual laboratory findings so interwoven with theoretic considerations, that most careful workers will wish more factual evidence of the efficacy of this purposeful therapy. For the great and glaring weakness of the book is that there is no proof that this detailed biochemical humoral medical therapeutic approach actually accomplishes anything, though the author states that of 167 treated patients approximately 85 per cent had improved hearing acuity and reported lessened tinnitus. There is in this entire book but one audiogram purporting to show improved hearing after almost a year of the author's type of therapy, and this one audiogram is itself open to critical doubt as to whether the gain shown is significant or meaningful.

On Hospitals. By S. S. Goldwater, M.D. [Collected Works.] Cloth. Price, $9. Pp. 395, with 34 illustrations. Macmillan Co., 60 Fifth Ave., New York 11, 1947.

This book is a collection of selected material from the many writings of the late Dr. S. S. Goldwater, whose accomplishments in the field of hospital administration and hospital planning gained worldwide recognition. For the convenience of the reader, the material has been arranged in five main sections, each representing a group of closely related subjects. The first section is concerned with hospital administration and organization and deals primarily with the function and duties of the hospital administrator. The organization of the medical staff is the main topic of the second section, which also describes the mutual responsibilities and interrelationships of the hospital and the staff physicians. In the third section the relationship of the hospital to the community as a whole is clearly interpreted. This concerns also the functions of the controlling board and the opportunities and responsibilities that come to those who are privileged to serve as hospital trustees. The principles of hospital planning are described in the fourth section, while in the fifth are detailed descriptions and outlines of representative hospital plans.

The book is a valuable addition to the literature of the hospital field and will serve as a convenient and authoritative reference for hospital administrators and consultants, students of hospital administration and other personnel interested in the planning, organization and maintenance of hospital service.

The Salicylates: A Critical Bibliographic Review. By Martin Gross, M.D., Research Assistant (Assistant Professor), Laboratory of Applied Physiology, Yale University, New Haven, Connecticut, and Leon A. Greenberg, Ph.D., Associate Professor, Applied Physiology, Yale University. With an introduction by Howard W. Haggard, M.D., Director, Laboratory of Applied Physiology, Yale University. Monographs of the Institute for the Study of Analgesic and Sedative Drugs, II. Cloth. Price, $6. Pp. 380, with 20 illustrations. Hillhouse Press, 432 Temple St., New Haven 11, Connecticut, 1948.

This book, the second in a series of monographs of the Institute for the Study of Analgesic and Sedative Drugs, is surely the most exhaustive critical bibliographic review of the salicylates that has ever been attempted. In his introduction to the book, Dr. Haggard says that the entire pertinent literature was reviewed in the original journals except for instances in which certain wartime issues of some foreign language journals were available in abstract only; however, the number of indicated abstract sources among the more than 4,000 references in the bibliography is extremely small.

The subject is presented under the following headings: historical; occurrence and properties of salicylates; the fate of salicylates in the body; pharmacology and toxicology of salicylates; therapeutic uses; salicylate poisoning, and the question of addiction or habituation. Of the 380 pages in the book, 193 are devoted to text, 174 to the bibliography and author index and 13 to the index of subjects.

This book will serve a useful purpose not only in bringing to hand the literature but in pointing out desirable lines of investigation and guiding away from duplication of study. More reviews of this nature are certainly to be desired in many pharmacologic fields.

Hungerkrankheit, Hungerödem, Hungertuberkulose: Historische, klinische, pathophysiologische und pathologisch-anatomische Studien und Beobachtungen an ehemaligen Insassen aus Konzentrationslagern. Von A. Hottinger et al. Mit Vorwort von Oberst K. Kistler, Kommandant der Militärsanitätsanstalt 4, Zurich. Cloth. Price, 8.50 Swiss francs. Pp. 297, with 171 illustrations. Benno Schwabe, Klosterberg 27, Basel, 10; Imported by Grune & Stratton, Inc., 381 Fourth Ave., New York 16. 1948.

Of all the evil fruits of war none is more certain—or more tragic—than famine. In World War II there was more systematic starvation than heretofore. In Germany it was organized into concentrations of misery with addresses like Belsen, Dachau, Buchenwald, Mauthausen and Auschwitz. Toward the end of 1944, however, the walls began to crack and an increasing trickle of human wreckage fled, or more often crawled, in search of food and help. The few who reached Switzerland found both in such frontier hospitals as at St. Gallen. With the final Nazi collapse the Swiss organized their Military Hospital in Herisau to accept some of the overflow from the flood which was engulfing France. The present book presents the findings and experiences obtained with 349 patients.

The book begins, appropriately, with a short but interesting historical essay on famine (by Salzmann). A group of chapters ("Klinische Kasuistik," by Hottinger) presents the general picture and the manifold complications of semistarvation and intercurrent disease. Numerous photographs intensify the vivid descriptions and fairly detailed case histories. The chapters (by Gsell) on the physiology and pathogenesis of "hunger disease" and hunger edema attempt a more scientific examination of the phenomena and the fundamental relationships. The difficulty of separating variables and achieving a rigorous analysis with the Swiss material will be appreciated when we note the heterogeneity of Gsell's patients. There were 24 males and 29 females, covering all ages except childhood, and their histories were very diverse; almost half of them (22) died in spite of good medical care. Ninety per cent of the patients at St. Gallen suffered from severe infections, often multiple, and only 1 patient was free from secondary infection. With such material, without adequate prestarvation standards, cause and effect are intermingled and precise analysis is impossible in terms of either basic mechanisms or statistical significance.

The pathologic anatomy seen in 53 autopsies, covering the age range from 11 to 90 years, is presented in 65 pages (by Uehlinger). The method is primarily descriptive, and quantitative measurements are given as examples. In this section, as elsewhere, in the book, we could wish for more systematic organization of quantitative data. The last section of the book, 50 pages on tuberculosis (by Labhart), conforms to the same general type of data and presentation. The great importance of tuberculosis in these patients is seen in the fact that the disease affected almost half of all patients at Herisau. Uncertainties of classification may explain discrepancies such as the statement on page 247 that there were 117 active cases and the summary statement that there were 124 active and 27 inactive cases of tuberculosis in the 296 patients at Herisau.

This book is the most ambitious recent attempt to review the subject of semistarvation. It does this successfully within the limitations of the classical clinical-pathologic approach. The paper, printing and binding are excellent, and this is important because the book, while not a classic, has permanent value.

The Venous Pulse and Its Graphic Recording. By Franz M. Groedel, *M.D., Attending Cardiologist, Beth David Hospital, New York.* Cloth. Price, $5.50. Pp. 223, with 121 illustrations. Brooklyn Medical Press, Inc., Box 99, Station H, New York 25, 1946.

The author has summarized in this monograph his observations of the venous pulse, and uses this as a basis for presenting some of his concepts. The booklet is beautifully prepared with clearly reproduced illustrations. This monograph is timely in bringing attention to a graphic method of heart examination which has been too much neglected recently. The literature is covered adequately and the text is profusely documented with illustrated case reports. The subject matter is divided into three sections: (1) Venous pulse, (2) the pneumocardiogram and (3) esophagocardiogram, and this is followed by an extensive bibliography. In the first and second sections, the author first develops the historical aspects and then describes the technic before considering the normal and abnormal configurations. The section on the esophocardiogram is rather brief.

It is regrettable that the subject matter at times becomes polemic, and that some of the concepts of the author will not have general acceptance. Nevertheless this book should be read by every cardiologist interested in obtaining a succinct summary of the author's contributions to this field.

The Illinois Hospital Survey and Plan. Illinois Department of Public Health, Roland R. Cross, M.D., Director. Paper. Pp. 179, with illustrations. Department of Public Health, Springfield, Ill., 1947.

This book contains the report of the Department of Public Health, designated by the Governor of Illinois as the state agency responsible for the study and planning of hospital facilities in accordance with the provisions of the Federal Hospital Survey and Construction Act. The specific plan for Illinois considers such factors as general hospital facilities and needs, tuberculosis sanatoriums, nervous and mental institutions, requirements for long term and convalescent patients, local health facilities, coordination of hospital services and the development of priority ratings for general hospital needs. Federal and state legislation pertinent to the hospital construction program is also described, as well as socioeconomic factors, population trends, transportation and communication facilities and the availability and distribution of professional personnel.

All who are interested in the planning and organization of hospital services will find in this book a wealth of information richly illustrated and supported by statistical tables and maps.

Modern Trends in Diagnostic Radiology. Edited by J. W. McLaren, M.A., M.R.C.S., L.R.C.P., Director, X-Ray (Diagnostic) Department, St. Thomas's Hospital, London. Cloth. Price, $12. Pp. 464, with 381 illustrations. Paul B. Hoeber, Inc., 49 E. 33rd St., New York 16, 1948.

This most welcome project contains a wisely selected series of contributions from scientists well qualified to write on the different aspects of the many advances in radiology. Scarcely a member of the medical profession could fail to find a lively interest and profit in perusing this book with particular reference to the chapters relating to his own special interest. The contribution of Baclesse, for interest, is an admirable consideration of the roentgenologic diagnosis of tumors of the pharynx and larynx such as can hardly be found in any other publication, certainly not in anything written in English. All through the book there are valuable chapters covering the newer phases of radiology in occupational disease, tumors, tuberculosis, sarcoidosis of the lungs, kymography and other methods in radiology of the heart; later developments in gastroenterology, renal tuberculosis, tumors of bone, spinal lesions, including disk pathology; the skull, including new developments in ventriculography, encephalography and cerebral angiography, and many other items of special interest. The book is a must for every radiologist.

Nuclear Radiation Physics. By *R. E. Lapp, Ph.D., and H. L. Andrews,* Ph.D. Cloth. Price, $6. Pp. 487, with illustrations. Prentice-Hall, Inc., 70 Fifth Ave., New York 11, 1948.

This volume is an outgrowth of an elementary manual written by the authors within the military establishment first on radiologic safety and later on radiologic defense. Nuclear physics is dealt with from the discovery of radioactivity by Becquerel, 1896, to the present time.

It is a well written text and contains many diagrams, tables and charts to supplement the information. One chapter is devoted to the makeup and function of the Geiger-Müller counter, which is one of the most important instruments used in the field. There is a chapter on health physics, written for a specialist skilled in protecting workers in atomic energy plants against stray radiation. Unless the general physician is fairly well versed in mathematics he is not likely to find the book easy reading. It is a textbook and not a popular treatise on the subject. Any one who has had a good course in college physics will enjoy working out the sample problems which are at the conclusion of each of the 18 chapters.

In view of the tremendous upsurge of the interest in biologic sciences in radioactive isotopes, this book is highly recommended to those physicians who are planning to specialize in the field.

Recent Advances in Surgery. By Harold C. Edwards, C.B.E., M.S., F.R.C.S., Surgeon and Lecturer in Surgery, King's College Hospital, London. Third edition. Fabrikoid. Price, $6.50. Pp. 437, with 131 illustrations. The Blakiston Co., 1012 Walnut St., Philadelphia 5, 1948.

The progress of surgery in all its branches has been outstanding during the past decade. In this small well written book Dr. Edwards and his collaborators attempt to summarize these advances and to make them readily available to the busy surgeon and general practitioner. The book is divided into six parts covering, among others, the following subjects: general considerations, alimentary tract, thorax, nervous system, blood vessels, ductless glands, sex hormones and cancer and radiotherapy in malignant disease. Cardiac pain, water balance, burns, postoperative pulmonary complications, anesthesia, aseptic anastomosis, vagotomy, physiologic gastrectomy, intravenous clotting and vascular injuries are a few of the subjects given special consideration. A number of illustrative drawings, diagrams and photographs are well distributed throughout the book. Good bibliographies are appended to each chapter.

The author has made an earnest attempt by digestion of a great deal of literature to keep the reader abreast of the times and present day surgical opinion.

Queries and Minor Notes

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

DEATH DURING ANESTHESIA

To the Editor:—This report is sent to you so that we may gain some information as to the cause of death. The child, aged 7, was seen three times one month previous to her admission to the hospital. She was in excellent physical condition and the only complaint was recurring tonsillitis. She was admitted to the hospital the morning of surgery, Aug. 31, 1948, without having taken food or water. Preoperative medication, 1/12 grain (5 mg.) morphine sulfate and 1/200 grain (0.3 mg.) atropine, was given about twenty minutes before surgery. An induction anesthetic of a small amount of ethyl chloride, followed by ether, was administered. The right tonsil was removed without bleeding; the left tonsil was removed and a hemostat was clamped on a small mucous membrane area of bleeding. At this time, possibly five minutes after complete anesthesia was obtained, the child's respirations became slow, possibly 8 to 10 a minute, pupils were dilated, the surface temperature was cold to touch and cyanosis was absent. Immediate attempts at resuscitation were given, including oxygen and carbon dioxide, nikethamide 1 cc. subsequently and 1 cc. in the heart muscles, and 1 cc. of epinephrine into the heart muscles and rectal dilation. Pulse was not obtained after the downward course started. Heart tones were questionable. After about forty minutes all attempts were abandoned, and the child was pronounced dead. Bleeding and coagulation time, August 27, was 4½ minutes. A chest and head autopsy was performed that evening. The report from the pathologist revealed definite tracheobronchitis. The death certificate was signed "cause of death undefined, occurring during anesthesia for T and A."

John B. Porter, M.D., Longview, Wash.

Answer.—Such an experience requires the consideration of several details concerning the preoperative medication as well as the administration of the ether anesthetic.

One-twelfth grain of morphine sulfate is a large dose for a child 7 years of age, assuming that she weighed about 45 to 50 pounds (20.4 to 22.7 Kg.). The full effect of this dosage could have been obtained at about the time the crisis occurred. However, the picture is not that of morphine poisoning alone, although observation of the pupils during the early stage of the induction of anesthesia would have given good evidence of a morphine effect had they been constricted. The dose of 1/200 grain of atropine (sulfate) was also a large dose for such a child, but it would probably be more likely that the widely dilated pupils were due to deep anesthesia.

The tracheobronchial findings at autopsy seem to verify the impression given on the death certificate, and in addition it might be added that the tracheobronchitis described was probably due to overconcentration of ether. Inasmuch as these findings were not localized in the posterior wall of the trachea, it might be assumed that accidental spilling of the ether into the trachea did not occur. This could have been a possibility if there were any unusual movement on the part of the patient or anesthetist. If the anesthesia was administered by a standard type anesthesia machine, it is a common experience that even though the ether is turned off, ether vapor continues to be supplied to the patient because the warming device causes continued vaporization of the ether. In order to make sure that the patient does not continue to inhale the ether vapor, the tube has to be entirely removed from the patient's mouth.

The autopsy findings seem to reveal more evidence of local reaction in the bronchioles and bronchi than could possibly be accounted for on any other basis than an external irritant. It would be interesting to know whether any one attending the operation would remember whether the patient was lying rotated more toward her right side just before the respirations slowed; e. g., when the operator was removing the right tonsil. If she was, this might explain how liquid ether could have caused greater damage to the right lung.

It would seem that ether was inadvertently aspirated by the patient or introduced accidentally while rotating the patient during administration of the anesthetic.

BLOOD SUGAR TEST

To the Editor:—Please give information as to technic of blood sugar tests using only 1 drop of blood. J. A. Speight, M.D., Rocky Mount, N. C.

Answer.—One of the widely used micro blood sugar methods is that of Folin and Malmros (*J. Biol. Chem.* 83: 115 [1929]), which was designed for 0.1 cc. of blood but which may be modified for 0.025 cc. of blood by merely reducing the amount of the protein precipitant, tungstic acid, from 10 cc. to 5 cc. This is the same amount of blood that is used for most hemoglobin methods. The results are reliable, but care must be taken in measuring out such a small amount of blood. Normal values by this method range from 75 to 100 mg. per hundred cubic centimeters of blood. If finger tip blood is used, the results will resemble venous blood only in the fasting state, since the former is mainly arterial blood. Following meals or during glucose tolerance tests, higher values will be obtained for finger tip blood than for venous blood.

EDEMA THROMBOPHLEBITIS

To the Editor:—In a married woman aged 69 years, thrombophlebitis of the right leg developed on September 14 without fever. She has been in bed since. She is free from pain, but the swelling remains. How soon should she be permitted to sit up or move about? What will facilitate the reduction of the swelling? Her history shows the following events in the past: thyroidectomy for toxic goiter in 1928; pernicious anemia since 1933; cerebral embolism, 1942, and cerebral hemorrhage, 1947. Her blood pressure is 130.

M.D., Pennsylvania.

Answer.—Although there is some difference of opinion relative to the length of time which a patient should be kept in bed after an attack of acute thrombophlebitis, most feel that it is unwise and unnecessary to keep patients in bed longer than eight to ten days provided that significant evidence of extension of the thrombophlebitis is absent. Although the inquiry does not state whether the phlebitis affected the superficial or the deep veins, it is assumed that the deep venous system was involved. The distinction is made chiefly because superficial phlebitis, unless it occurs in varicose veins, may be a manifestation of cancer and necessitates careful search for cancer, particularly of the pancreas, stomach and lung.

Almost invariably edema which follows acute thrombophlebitis may be made to disappear by elevation of the extremity when the patient is in bed. The problem which remains is that of adequate control of the swelling, not because the swelling itself is of significance, but because it is a manifestation of impaired venous circulation which usually leads to such complications as varicose veins, stasis dermatitis and ulceration. The measure of adequate support is its effectiveness in controlling swelling. In some instances this may be accomplished by the use of elastic bandages; in other instances the use of pure gum rubber bandages (Davol Rubber Company, Providence, R. I.) 3 inches (7.6 cm.) wide and 15 feet (4.57 meters) long is advisable. In any event, the bandages are applied like puttees and are worn during activity. There is no need for the application of bandages during sleep. The patient should go without the bandage one day out of each month and continue its use only if edema results. In more than half of all instances of deep thrombophlebitis it is possible to discontinue the use of a bandage within three to six months.

PURPURA SIMPLEX

To the Editor:—Patients are occasionally seen whose most characteristic finding is that of extensive subcutaneous hemorrhages or ecchymoses. Often a determining factor cannot be observed, or the hemorrhage appears to be much more extensive than such a cause would indicate. The literature fails to explain this phenomenon, which is presumably related to the purpura. Please give information relative to this problem.

M.D., Illinois.

Answer.—It is assumed that this question refers to persons who manifest purpura over a period of years without other evidence of a bleeding tendency and who have no other signs of disease of the blood or blood vessels. The bleeding and clotting time, clot retraction and the platelet count are normal. In these patients the purpura is apparently the result of abnormal fragility of the smaller blood vessels. Atropine, bismuth, chloral hydrate, mercury, acetophenetidin and the salicylates have been reported to cause such a condition. When there is associated hemorrhage into the bowel, joints or elsewhere the condition is classified as Schönlein-Henoch's purpura and is thought to be allergic in nature.

Although it is possible that a deficiency in vitamin D may be related to such states, this has not been established. Many cases fall into the group recently described by Davis (*Lancet* **1**:145, 1941) as "hereditary familial purpura simplex," occurring particularly in women at the climacteric.

From the diagnostic point of view it is important to demonstrate that the clotting mechanism is normal. If the condition is chronic and the patient otherwise healthy the patient can be assured that the prognosis is entirely good. No effectiv therapy is known.

DIFFERENTIAL DIAGNOSIS IN BONE LESION

To the Editor:—A 20 year old female graduate nurse first noted onset of headaches in December 1947 at the same time that she discovered a depression in the left parietal bone. About five months previously she had bumped her head on a bed post in the region of the depression. The trauma had been regarded as trivial. Three months later severe headaches returned, localized in the left side of the head and radiating from the eye backward to the neck. Vision, position sense and gait are unaffected. One and one-half years ago she had pain in the left leg in the region of the patella accompanied by a slight effusion in the knee joint. Roentgenograms of the lower part of the back, the pelvis and the legs at that time were normal. With infra-red treatments this cleared promptly but six months ago the right leg began to "burn" from hip to foot on the anterior surface. Numbness and back pain are absent. Symptoms are worse during rainy weather. The patient is moderately obese. There is a circular depression about the size of a quarter and with a tender edge in the left parietal bone. Physical condition otherwise is within normal limits. Blood chemical and serologic data are within normal limits. Complete skeletal roentgenograms including the sinuses are normal except for the skull: In the left parietal region, there is a large area of bone destruction which measures 5.5 cm. in its maximal diameter. It is irregular in its outline and involves both the inner and outer tables of the skull. This is consistent with a primary tumor, probably an eosinophilic granuloma. A biopsy was taken from a representative area. It showed only minute fragments of normal bone and fibrous tissue—no evidence of eosinophilic granuloma. In view of the negative biopsy, should the patient be subjected to x-ray therapy?

M.D., New York.

Answer.—Any causal relation with the vague remembrance of trivial trauma may be discarded at once. Any connection between the local skull findings and the pain in leg, patella and knee joint in the face of prompt recovery and negative roentgenologic findings likewise is lacking. The negative findings (complete skeletal) reported of the roentgen examination as to any pathologic changes anywhere except the area of bone change in the parietal region are helpful in possibly eliminating a diagnosis of osteitis fibrosa cystica, multiple myeloma or multiple metastatic growths in the bones. Without histologic evidence of eosinophilic granuloma the diagnosis might narrow down to fibrous dysplasia of bone, Hand-Schüller-Christian disease or an as yet early myeloma. In Albright's syndrome there may be sexual precocity and usually pigmentation of the skin, which points are not mentioned in the query. A differential diagnosis might include simple cystic disease of bone, hyperthyroidism, neurofibromatoses (von Recklinghausen's disease), dischondroplasia (Ollier's disease), Hand-Christian-Schüller disease, early osteitis deformans (Paget's disease), osteoid osteoma, or a malignant (metastatic) bone lesion; multiple myeloma might be eliminated by sternal aspiration and cell study—with a nonresistant sternum on puncture and myeloma cells in the marrow material.

The inquirer might look for pigmented skin spots, for high blood urea; he should repeat study of skeletal bones to establish fibrous dysplasia of bone and enquire about history of renal colic or calculi found in hyperparathyroidism. Also he may search in the neck for nodules in the thyroid area and inquire about polydipsia or polyuria or absorption of the lamina dura shown by dental films. He may repeat studies of the blood serum calcium looking for higher ratios. It is said that a high total blood protein may explain a high blood calcium due to myeloma or sarcoidosis rather than parathyroid disease.

From the amount of pain mentioned one must consider osteoid osteoma, which is usually painful and contains multinucleated giant cells and irregularly calcified osteoid tissue. To date no one has reported an instance in the cranium.

In Schüller-Christian disease there may be pigmentation and polydipsia and often exophthalmus with diabetes insipidus along with calvarial defects and a finding of eosinophils locally in the bone lesions. Ackerman reported involvement of the diaphragm in a case. Most of the instances are multiple bone lesions with histologic changes characteristic of eosinophilic granuloma.

Consultant's advice should be sought, bearing in mind some of the mentioned points in additional examination. On the facts given, prognosis is good.

PROTEIN-BOUND IODINE

To the Editor:—Does administration of iodine, such as by medication or in the Graham Cole test, influence the level of protein-bound iodine in the blood so as to confuse the diagnosis of hyperthyroidism?

M.D., California.

Answer.—The administration of iodine does raise the level of protein-bound iodine. As a result, the determination of protein-bound iodine is not of much value in patients who have been receiving iodine. Data are not available concerning the influence of iodine in the dye used for the Graham Cole test.

PSORIASIS OF SCALP

To the Editor:—Has any satisfactory therapy been developed for psoriasis of the scalp?

Willis P. Baker, M.D., Santa Ana, Calif.

Answer.—For large numbers of cases, the lesions on the scalp, as elsewhere on the skin, can be entirely cleared or improved. The scalp in chronic or inveterate psoriasis is a site particularly resistant to treatment. Some of the more effective agents, such as chrysarobin and tar, which may be useful elsewhere, are withheld from the scalp. Ordinarily, local treatment of psoriasis of the scalp consists of 5 to 10 per cent of ammoniated mercury ointment with or without the addition of 3 to 5 per cent salicylic acid. A water-miscible base is advantageous toward easier removal by washing. If parts other than the scalp are involved, they should receive appropriate therapy simultaneously. The general momentum acquired by improvement of the less resistant areas seems to carry over to those where more difficulty is commonly encountered. It may even be worth while to get movement away from dead center by the use of roentgen exposures. This should be done cautiously, only by the expert and as an initiating measure. These precautions are necessary to prevent loss of hair, which might result after injudicious use of this modality. Ultraviolet rays, on the other hand, are safe. The face, though, should be protected, because it is much more sensitive to their effects than is the scalp. Systemic treatments, each of which is helpful at times, should be given in conjunction. Any attention which will improve the physical background of the patient, such as treatment of associated anemia, should redound to the benefit of the scalp condition. While no efficient revolutionary remedies have been introduced recently, by and large, a skilful practitioner can achieve satisfactory results in the large majority of patients with psoriasis.

FRACTURES AND CALCIUM METABOLISM IN THE AGED

To the Editor:—Would the frequent fractures of the hip in older persons be prevented by a daily intake of milk calcium throughout life?

Anna E. R. Robinson, M.D., Brooklyn.

Answer.—The American diet is probably more often deficient in calcium than in any other chemical element. Among elderly persons (women more than men) senile osteoporosis is frequently found. Frequent hip fractures encountered in older persons may be due to prolonged suboptimal intakes of calcium. The Food and Nutrition Board of the National Research Council recognizes that a liberal amount of calcium is necessary in the diet. The recommended allowance of calcium for adults has been increased from 0.8 to 1.0 mg. per day. Diets containing little or no milk will probably be deficient in calcium.

Dr. F. J. Stare has said, "It was a surprise to see that the majority of roentgen studies on adults past the age of 45-50 years showed considerable demineralization of bone, and one wondered whether low dietary intake of calcium or of vitamin D, over many years, might not have been prominent causative factors in the demineralization." Calcium metabolism in the adult proceeds slowly. If the diet contains an inadequate amount of calcium the blood will take the needed amount from the bones, thus significantly weakening them over a period of years.

A liberal daily source of calcium continued throughout life should tend to minimize demineralization of the bones and consequently reduce the number of fractures prevalent in older persons.

DIPHENYLHYDANTOIN SODIUM IN PREGNANCY

To the Editor:—1. Is there a contraindication to the use of "dilantin sodium" (diphenylhydantoin sodium) during pregnancy?

2. In a patient with migraine, who is pregnant, is "gynergen" (ergotamine tartrate) contraindicated at all times, or is there less risk in the first trimester?

M.D., Massachusetts.

Answer.—1. Reactions to diphenylhydantoin sodium may occur in any group of cases, and therefore its use should be begun with caution whether the patient is pregnant or not. In pregnancy, even greater caution should be exercised. If a patient has been receiving diphenylhydantoin without reaction, pregnancy should not be expected to cause such reactions.

2. Ergotamine tartrate is contraindicated throughout pregnancy. This does not mean that abortion will necessarily follow its use, but it certainly does tend to produce uterine contractions. The longer the duration of pregnancy, the greater this effect is manifested, and a ruptured uterus may follow its use.

DIAGNOSIS AND TREATMENT OF OCCUPATIONAL METAL POISONING

LEONARD GREENBURG, M.D.
New York

The rapid development of American technology during and following the last war has not only taxed the skills of the scientist and the engineer but has also created new problems for the physician. One has only to think of the preventive, diagnostic and therapeutic concepts which the field of artificial radioactivity has created to realize how complex the practice of medicine has become and will continue. These new problems are not only the province of the radiation specialist and industrial hygienist; the general practitioner too must be alerted to the changes brought about by the use of new substances and processes in industry, since they are responsible for a changing picture of disease and illness among the working population.

Of importance to the general practitioner are the problems of occupational metal poisoning. The introduction of many new alloys and industrial processes has created environmental conditions wherein workers are often subjected to the dusts and fumes of toxic metals and the mists or gases of metallic compounds. Rare metals which a few years ago were laboratory curiosities have suddenly assumed important roles in industry. As a result, new disease entities are being encountered; for example, the pathologic manifestations resulting from exposure to beryllium, a metal almost unknown in industry as recently as ten years ago, and in addition exposures to old offenders are revealed in unexpected form.

The general practitioner may ask: "But why does this concern us? Are not these the problems of the industrial hygienist or of the plant physician?" The industrial diseases do not, as a rule, stand out as distinct entities which are immediately referred to the specialist; more often they first come to the attention of the family physician as an indefinite acute or chronic complaint, which, unless the occupational exposure is carefully evaluated, results in diagnosis and treatment as a nonoccupational illness. In their ability to affect many organ systems and to imitate other diseases, the industrial illnesses take second place to none, not even syphilis. Many a worker has been subjected to a laparotomy for suspected appendicitis when he was actually suffering from lead poisoning of obscure occupational origin or treated with penicillin for bacterial pneumonia when he was really the victim of exposure to cadium fumes.

The first problem confronting the general practitioner is, therefore, one of diagnosis.

THE DIAGNOSIS OF THE OCCUPATIONAL DISEASE

How does one arrive at a diagnosis of the occupational disease? What does one look for, and how is the occupational disease differentiated from the nonindustrial one?

It would not be an uninteresting task to write a lengthy dissertation on the mental steps involved in the making of a medical diagnosis. Time does not permit such a pleasant diversion. Suffice it to say that the exposure of large numbers of industrial workers to the special conditions under which they work and to toxic substances with which they come in contact makes it essential that a careful and complete occupational history be taken and that the physician possess a knowledge of the toxic effects of the substances to which workers are exposed.

The Occupational History.—The importance of taking a complete occupational history cannot be overstressed. It is necessary to know not only what the patient's job is but also specifically what materials he handles, what processes he performs on the materials and what his working environment is. When a man states that he is a lead burner, a diagnosis of lead poisoning may become obvious, but when he says that he is a furnace tender in a brass foundry, it may require considerable detailed questioning to elicit a history of a no less significant exposure to lead fumes. Unfortunately, often the worker himself may not be aware of the nature of the materials which he is handling; the furnace tender may be totally oblivious of the high percentage of lead in the brass he is handling or of the smaller amounts of arsenic, beryllium or selenium which may be present.

The occupational history, therefore, should include a complete knowledge not only of the job but also of the materials handled in the plant by the worker and by other closely associated workers. Not only is it necessary to obtain this information for his current job, but all his previous positions of employment should be reviewed in order to evaluate the cumulative effects of exposure in the past. Frequently, because of the lack of detailed knowledge on the part of the worker, the physician may have to extend his inquiries to the plant itself. In many instances, it may be possible to obtain the necessary information from the plant physician or the safety engineer. In others, an investigation on the site may be indicated. Often the state or local division of industrial hygiene may be of service in this respect.

Dr. Greenburg is executive director of the Division of Industrial Hygiene and Safety Standards, New York State Department of Labor.

Read in a joint meeting of the Section on General Practice and the Section on Preventive and Industrial Medicine and Public Health at the Ninety-Seventh Annual Session of the American Medical Association, Chicago, June 23, 1948.

This may sound formidable, but in most instances the taking of the occupational history may be done rather simply by noting, in addition to the usual personal information, the following: name of company, process, job, materials handled and date of beginning and ending of employment. The history should start with the present job and work backward chronologically, if possible, ending with the first employment of the patient.

It is of fundamental importance that the physician know, or at least be familiar with, the signs or symptoms of the commoner occupational diseases. Without such knowledge, it is impossible for the practitioner to tie together in his mind the present complaint of the patient and the causal agent, the industrial exposure.

For this reason, I should like to summarize briefly the more or less common metallic exposures which may be associated with various occupations and the systems affected by each of these metals. It is not to be hoped that this brief paper can fully acquaint physicians with all the hazards and their signs and symptoms, but I would at least like to give an impression of the broad scope of the field and of the variety of aspects which the industrial diseases may present.

HAZARDOUS METALLIC EXPOSURES

Foremost among the hazardous metallic exposures are those to which smelters, refiners and workers in founderies are subject. Many of these hazards are immediately apparent, as, for instance, in the smelting and refining of lead, mercury or beryllium, but often the really dangerous metal may be present only as an impurity. Copper, for example, is considered a nontoxic metal, but many of its ores contain sufficient arsenic to present a real hazard to workers handling them. The addition of lead, and more recently beryllium and selenium, to brass and bronze in order to achieve special properties may, in addition, create a real danger. Similarly, manganese, chromium, selenium and beryllium have all been used in the manufacture of special alloy steels. The exposure may occur not only in the process of melting and pouring, when the toxic metals are liberated as fumes, but also from sawing or grinding off gates and risers, tumbling, cutting up ingots and handling scrap, all of which may create toxic dusts. In the course of refining some of the metals, soluble salts may be formed as an intermediate step, with the dissemination of dusts when dry and mists when in solution.

These products of the mills and foundries then undergo a variety of operations. They may be machined, ground or polished, yielding dusts in the process. Surfaces may be plated with chromium or cadmium, with the production of a hazard from the metallic mists. The increased use of welding has created a fume hazard in many shops, not only from the toxic metals in many of the alloys but also from metals which have been plated, particularly with cadmium. Riveting, welding and acetylene torch cutting of structural steel which has been painted with red lead may liberate lead fumes. Soldering and lead burning often expose a worker to lead and antimony.

Toxic exposures to metals occur in many other occupations in which the association is more devious. The incidence of lead colic among painters is well known, but the fact that antimony, mercury, arsenic, chromium and selenium are also used in the preparation of various pigments and may be a hazard to the manufacturers of such paints is often much less obvious. The lead and antimony in type metal create a danger in many branches of the printing industry, especially in casting operations on a large scale. Lead, antimony, arsenic and selenium are common ingredients of ceramic glazes, and recently beryllium oxide has found use as a ceramic in instances in which high-melting and heat-conducting characteristics are essential. The use of lead salts in the formulas of special glasses is often overlooked as an industrial hazard because of the preponderant exposure to silica dusts. Mercury is finding increasing use in all types of precision instruments and electrical equipment, including many types of switches, electronic tubes and lamps, and in paints and insecticides. More recently there is the serious hazard presented by the beryllium salts used as phosphors in the manufacture of fluorescent lamps, neon signs and cathode ray tubes.

Since the two following articles will deal with the problem of lead at some length, I will not discuss it here other than to mention that lead may be responsible for a multiplicity of general, gastrointestinal and neurologic disorders, ranging from fatigue and anemia to colic and encephalitis.

Arsenic.—Arsenic may cause either local or systemic manifestations. The local ones consist of cutaneous manifestations of various types, such as dermatitis, eczema, ulcers, keratosis, scleroderma and bronzing. Frequently, the eyelids and mucous membranes may be affected. If not properly treated, the lesions may undergo carcinomatous degeneration. Frequently, arsenic which is absorbed into the body is excreted by the sweat glands, so that lesions of the skin develop in moist areas, such as the scrotum or axilla, as well as on exposed surfaces. Dryness of the mouth and throat and hoarseness may result. Systemically, the metal causes trophic changes in the hair and nails (because of its affinity for sulphur), neuralgia and multiple neuritis, with slight motor paralysis, gastric symptoms and anemia. Arsine or hydrogen arsinide, which is a gas often accidentally liberated by the contact of arsenic with an acid, has a rapid and violent hemolytic effect and may cause severe anemia with jaundice and hemoglobinuria. Both acute and chronic cases of exposure can usually be confirmed by the presence of arsenic in the urine and delayed chronic cases by analysis of the hair and nails.

Cadmium.—Cadmium produces severe systemic reactions, but since the primary industrial exposure is by the inhalation of fumes and dusts most cases usually involve the respiratory tract predominantly. It first causes a dry or sore throat, followed by headache and dizziness. Subsequently, severe constricting pain in the chest and dyspnea develop, secondary to acute pulmonary inflammation and edema with pleurisy. The mortality is high, but recovery, when it occurs, is complete. Cloudy swelling of the liver and spleen have been noted at autopsy. When ingested, the metal causes severe epigastric distress and vomiting.

Beryllium.—The addition of beryllium to the list of toxic industrial metals has been so recent that there is still some confusion in the clinical picture. Locally, it may cause urticaria, which progresses to papular and vesicular dermatitis and sometimes to ulceration. Particles embedded under the skin produce granulomatous lesions or indolent ulcers. The most important effects, however, are on the respiratory tract. The more soluble forms produce an irritation varying from mild pharyngitis to severe bronchitis and pneumonitis with pulmonary edema. These usually appear a few days or weeks after exposure, and unless death from acute pulmonary disease supervenes they resolve completely in one to two months. The insoluble salts appear to cause a chronic pulmonary granulomatosis, characterized by diffuse thickening of the alveolar walls, monocytic infiltration and unit lesions consisting of aggregations of histiocytes which undergo hyaline degeneration and containing the Langhans type of giant cells and inclusion bodies. Roentgenologic findings consist of a fine soft granularity in the early cases, which progresses to diffuse reticular patterns and then to uniformly distributed nodules 1 to 5 mm. in diameter in the advanced stage of the disease. This form of the disease often does not show up until years after the initial exposure and sometimes several years after cessation of contact with the toxic agent. There results a marked diminution of respiratory reserve, with high mortality and almost invariably permanent disability. Granulomas are also occasionally seen subcutaneously and in the liver. More recently, a form of the disease falling between the acute and chronic types, with a longer latent period and a longer period of convalescence but no permanent pulmonary changes, has been reported due to the inhalation of fumes and dust of the pure metal and oxide.

Mercury.—Mercury, like lead, is a metal which is principally absorbed through the respiratory tract but which exerts its toxic effects on several organ systems. Primarily, it is a poison which affects the central nervous system. It produces an intention tremor similar to that seen in paralysis agitans. This may affect the hands, limbs, head, lips, tongue or jaw, either unilaterally or bilaterally. The paralysis is readily demonstrated by the worker's handwriting. In addition, various psychic disturbances, such as unrest, irritability, depression and a loss of concentrating power and self confidence, may be present. Occasionally, generalized weakness, pains in the chest and cramps in the leg muscles may develop. Nephrosis or nephritis, with considerable albuminuria, is a frequent, and sometimes only, evidence of intoxication. Gastrointestinal disturbances, such as nausea, diarrhea or constipation, vomiting and stomatitis, sometimes occur, particularly in the presence of poor oral hygiene. Diagnosis is sometimes aided by a determination of the amount of mercury in the urine, but there is no definite relationship between the amount found and the degree of poisoning.

Manganese.—The effects of manganese poisoning are limited almost exclusively to the central nervous system. There is a disturbance of gait, with stiffness of the legs and a tendency to drag the feet, which is characteristic and which makes it extremely difficult for the persons affected to walk backward or up an inclined surface. Masklike facies, increased fatigability and sleepiness have also been noted. The effects are usually permanent except when the exposure has been brief. Degenerative changes in the basal ganglions have been found at autopsy. Other effects include neutropenia, occasional mild hemoglobinemia and a slight lowering of the blood calcium content. Determination of manganese in the urine is useful in demonstrating a past or present exposure, since the metal is stored in the lungs and slowly excreted by the kidneys, but the amount has no relationship to the degree of intoxication.

Chromium.—The toxic effects of chromium are mainly manifested by chromic acid and its salts. The most common is the development of indolent ulcers on the skin or the mucous membranes, particularly on the dorsum of the fingers, hands or arms, the nasal mucosa or the eyelids. They are deep, with thickened rounded edges, and are relatively painless, with little evidence of inflammation. Those in the nose frequently result in perforation of the septum. Less common manifestations are allergic reactions, such as dermatitis and asthma. Recently, chromium has been indicted as an etiologic agent in cancer of the lung, particularly among those engaged in mining and processing of chromate ores.

Selenium.—Selenium is one of the lesser known metals whose toxic properties have not yet been adequately evaluated. It appears to cause respiratory irritation, with cough and pulmonary edema, gastrointestinal symptoms including nausea, vomiting and abdominal cramps and disturbances of the central nervous system such as convulsions and loss of reflexes. There is some evidence that chronic exposure may be an etiologic factor in the occurrence of tooth decay, arthritis and disease of the liver. Absorption of selenium can be readily demonstrated by its presence in the urine and by a garlic odor of the breath.

The oxide fumes of certain metals, principally zinc but also mercury, tin and copper, are known to produce a physiologic response known as metal fume fever. It occurs only with fumes from such operations as casting or welding and cannot be demonstrated with dusts of the metals or their oxides. The symptoms resemble those of influenza, with chills, fever, malaise, generalized aches, dry throat, nonproductive cough and sometimes nausea and vomiting. Other than leukocytosis, there are no pathologic changes, and no chronic effects or sequelae have ever been noted. The condition clears rapidly after removal from exposure.

Tellurium, thallium and vanadium are believed to have effects similar to those of selenium, with an additional depilatory effect ascribed to thallium, but, industrially, few exposures have been described as yet. Aluminum and magnesium are considered toxicologically inert, although when metal chips become lodged under the skin they produce local subcutaneous emphysema and necrosis from the liberation of hydrogen by reaction with the body fluids. Iron may produce a condition known as siderosis because of the deposition of dusts or fumes in the lungs, but this is considered an inert form of pneumonoconiosis which does not cause disability. Many types of disease have been attributed to copper in the past, but almost all have since been shown to be the result of handling the accompanying lead or arsenic, either in alloy form or as a contaminant, and no industrial hazards from pure copper other than metal fume fever have ever been proved. Silver, even in nonorganic combination, has been shown to cause argyrosis when inhaled or ingested, but the occurrence of industrial exposures has been relatively rare.

THE TREATMENT OF THE METALLIC POISONS

With the diagnosis of poisoning by a toxic metal established, what is there to offer in the way of treatment? First and foremost, there must be insistence on complete removal from exposure. All the toxic metals, other than those producing fume fever, are cumulative in the body, and a mild intoxication, which on the basis of symptoms would not prevent a worker from continuing on the job, might readily become serious if further exposure is continued. When it is possible to transfer the employee to an exposure-free job, this might be considered, but care must be taken to insure that this is not work at a lower level of exposure which would be harmless only to someone who had not accumulated toxic amounts of the metal. Once the affected person is removed from exposure, most of the conditions will gradually clear up, as the body slowly detoxifies itself by the normal avenues of excretion. When irreversible changes have taken place, such as degeneration of nervous tissue or pulmonary fibrosis, the worker may not show improvement with removal from exposure, but at least further deterioration may be prevented.

Other measures of importance in the general treatment of toxic metal poisoning are those which promote recovery and aid in the elimination of the substances. Adequate rest and a nutritious diet are essential. When the symptoms are severe enough, bed rest is frequently indicated. The diet should be supplemented by vitamins, if necessary. Symptomatic treatment, such as sedatives for cough or pain, is always in order.

Specifically, there are a few drugs in the physician's armamentarium which are of definite or possible value in the case of certain metals. I will not enter into a discussion here of the various types of treatment advocated in lead poisoning, as this will be covered in detail by one of the later speakers. When respiratory embarrassment occurs, as in the presence of pulmonary edema from acute beryllium, cadmium or selenium intoxication or of the alveolar pathologic changes caused by chronic beryllium poisoning, oxygen will often be helpful in tiding the patient over the most severe phases of the disease. Because of the low blood calcium content demonstrated in cases of manganese poisoning, large oral doses of its salts have been recommended; intramuscular injections of liver extract are also claimed to be beneficial in this disease. Sodium thiosulfate given intravenously has been used with beneficial results in both manganese poisoning and mercury poisoning. The nervous disorders of the latter have been helped by the use of drugs of the atropine group, notably scopolamine or stramonium, and, more recently, by administration of amphetamine sulfate. Local cutaneous reactions are usually best treated palliatively. Chrome ulcers will heal more readily if the salts in them are reduced: scrubbing with sodium hyposulfite solution or its application in the form of wet dressings will frequently açcomplish healing. Débridement or complete excision may occasionally be necessary; this treatment is always indicated for the subcutaneous lesions produced by beryllium or the other light metals.

During the last war, British scientists developed 2,3-dimercaptopropanol, more familiarly known as BAL, as an antidote for the toxic effects of arsenic compounds, at that time feared principally as war gases, such as lewisite. This compound acts apparently by the great attraction of its sulfhydryl radicals for arsenic, which would otherwise combine with the sulfur-containing molecules of the body tissues and destroy their activity. It has proved effective in the treatment of industrial arsenic poisoning, both for the systemic effects when given intramuscularly and for the skin and eye reactions when applied locally. Some side reactions from its use have been noted, but they are rarely severe enough to force discontinuance when the dosage is carefully controlled. It has also been shown to be effective in the treatment of acute mercury poisoning.

In conclusion, then, the toxic metals constitute an increasing industrial hazard because of the many new uses to which metals are being put. Prompt recognition of the industrial origin of the many obscure signs and symptoms, referable to almost any organ system of the body, is essential if the disease is to be diagnosed before irreversible changes have taken place. The principal aids to proper diagnosis are a good occupational history, with a thorough investigation of the materials to which the worker has been exposed, and an adequate knowledge by the physician of the toxicology of those materials. Once the diagnosis has been established, therapy should be directed to removal of the patient from any further contact with the toxic substance, promotion of its elimination through natural channels, rest and general supportive and palliative therapy. A few specific substances have been shown to be effective for certain metals, notably BAL in the treatment of arsenic poisoning and acute mercury poisoning. But the best control of toxic metal poisoning lies in the prevention of excessive exposures by industrial hygiene for which the plant physician, the industrial hygienist and the safety engineer must assume some responsibility.

DIFFERENTIAL DIAGNOSIS OF LEAD POISONING

Accepted Laboratory Criteria

ELSTON L. BELKNAP, M.D.
Milwaukee

Twenty-three years ago, as an assistant resident in medicine, my experience with lead poisoning began. I was called on to diagnose and treat lead colic, caused by the inhalation of lead dust in the manufacture of storage batteries, in a small group of patients. Fortunately for them, the monograph on lead by Aub and his associates had just been published.[1] Using his clinical method of study and his uniformly effective treatment with intravenous injections of calcium, I was able to return 6 of the men rapidly to their work.[2] Since then, I have limited my practice to internal medicine, and have also had the opportunity to study several hundred other lead workers, subject to nearly every known type and intensity of industrial exposure to lead. For eighteen years, at the time of this report, I have been responsible for the health of 80 to 100 lead workers in the storage battery industry. In this period, there has never been a time when some of the men have not had a lead line, indicating considerable absorption of lead.

In spite of increasing attention to mechanical means for the prevention of absorption of lead, occasions have arisen when heavy exposure has been temporarily unavoidable. These have been due to the element of human inability to follow suggestions, or have occurred when, during installation, new machines were temporarily not covered with protective devices.

When I first took over the responsibility for the health of this group, there was an incidence of disabling lead poisoning of 20 men per hundred each year.[3] In the past eleven years, I have had no cases of

---

disability due to lead intoxication. Now, after twenty-three years, I am still depending primarily on Aub's clinical diagnostic picture and plan of treatment, coupled with physical and laboratory examinations, performed periodically every two to four weeks. A somewhat similar, and very excellent, plan for an individual screening record for lead workers was recently reported by Silson, of the Medical Unit, Division of Industrial Hygiene and Safety Standards of the New York State Department of Labor.[4]

CLINICAL DIAGNOSIS

It is my conviction that the diagnosis of lead intoxication, the commonest industrial poisoning, is primarily a clinical problem. It is certainly one that is first met by the general practitioner, with increasing frequency, in our modern chemical industry. He is the man to whom the patient turns first. Can the physician in general practice, however, make a satisfactory diagnosis? It is my opinion that he can make the correct diagnosis as to the presence or absence of lead poisoning in 90 per cent of the cases. He must use the skills available to every physician, namely, a detailed history, careful physical examination and observation for lead line and wrist drop, together with studies of the blood, especially the determination of hemoglobin and the increase in stippled cells. First, he should study up on the subject, because most medical schools give no practical instruction in occupational medicine. Second, he can be quickly trained to take a good occupational history as well as a complete general history. He should be able to conduct a thorough physical examination, including a search for a lead line, and to test for true paralysis on extension of the wrist. Every medical student is now instructed in how to stain blood smears and make stippled cell counts or, at least, trained to evaluate reports of such studies when received from a laboratory.

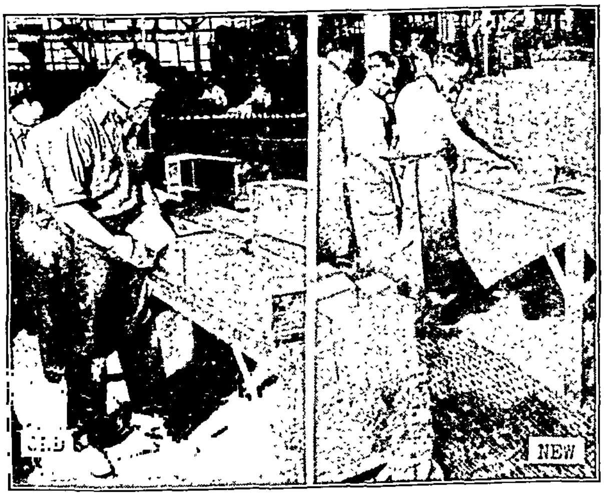

Fig. 1.—In firsthand inspection of the place of work, correlated with the finding of the lead line and stippled cells in the worker, the physician can recognize danger in an occupational exposure. Frequently, he can recommend protective engineering devices which will keep the worker healthy. Note the perforated work tables, with downdraft suction, and slotted floor mats to help control the lead dust at its source.

Distinction Between Lead Absorption and Lead Intoxication.—The physician must first have clearly in mind the distinction between lead absorption and lead intoxication. Lead absorption means absorption of lead into the system by inhalation or by ingestion. This lead absorption is shown as well by the determination of a lead line and a few stippled cells as it is by quantitative determination of lead in the urine and blood, and the process is much simpler.

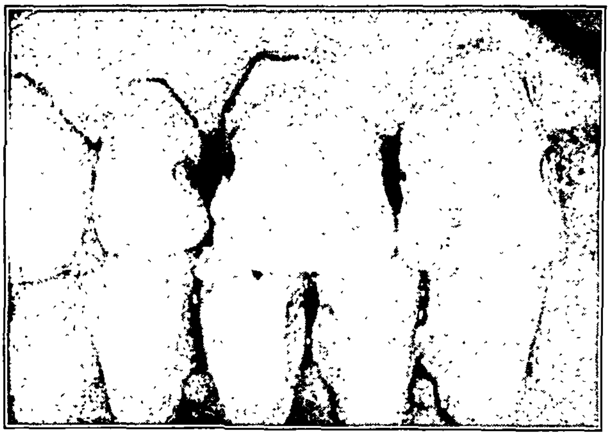

Fig. 2.—Under a hand lens the lead line of blue-black lead sulfide, actually deposited in the gums immediately opposite to the teeth, appears as a clear row of dots or vertical streaks. The worker had continuous heavy exposure to lead for one month before appearance of the lead line as 3 plus (definite dotting opposite 3 teeth).

Lead intoxication, or true lead poisoning, is present when the patient shows definite evidence of illness with disability, due to one of three main types of lead intoxication. These are lead colic, the commonest type, lead palsy and lead encephalopathy, much rarer and more serious types of lead poisoning.

Let us now consider the steps with which the practicing physician can make a diagnosis of lead poisoning. If possible, he should analyze at firsthand the probable exposure of the worker, in a personal tour of his place of work, just as Ramazzini advised two hundred and fifty years ago. The alert doctor of medicine does not require an engineering degree to see the advantage of downdraft, perforated work tables and slotted floor mats in helping to control lead dust at its source (fig. 1). If the physician studies the work place, as well as the worker, he may make up his mind from direct observation whether the occupational conditions contributed to the lead absorption that may be present.

Lead Line.—The simplest way of proving lead absorption (not lead poisoning) in the individual patient is to demonstrate a true lead line of the gums. The physician must be in a position to say more than "There is a suggestive lead line" or "The gums are somewhat bluish gray." Although I have heard some experts on lead poisoning complain that they were not sure they could recognize a lead line, it is not difficult to demonstrate its presence. With simple, though adequate, study under a small hand lens, using a head mirror and good illumination, the lead line appears as in figure 2. It is blue-black lead sulfide, actually deposited in the substance of the gums next to the teeth. Under the lens, the lead sulfide is seen as a clear row of dots or vertical streaks. A lead line is best seen in gums with acute pyorrhea, next to a carious tooth, behind the front teeth or next to the molars, where aeration is rarely good. One must be certain that the man is not receiving bismuth for syphilis, as a bismuth line is indistinguishable from a lead line. However, a lead line is not easily seen in mouths where there is good oral hygiene, without pyorrhea or decayed teeth.

---

LABORATORY EXAMINATIONS

Stippled Cells.—In the case of a clean mouth with no lead line, the diagnosis may depend chiefly on the presence of stippled cells. There are approximately 200 red blood cells per oil immersion field, so that in 50 such fields there are about 10,000 red cells. To arrive at the number of stippled cells per million, one multiplies by 100 the number of stippled cells found in 50 fields.

There are those who say that stippled cells are of no diagnostic importance because they are not specific for lead poisoning. I believe that no qualified expert in this field has ever said that they were specific or pathognomonic. Wintrobe stated the belief that the finding of any stippled cells in the blood of a normal person is infrequent.[5] However, according to Machle,[6] there may be a few stippled cells in the normal person, as from 3 to 7 per 50 fields, the equivalent of about 300 to 700 per million red blood cells. It is well known that any condition which causes a strain on the bone marrow, such as severe secondary or primary anemia or a debilitating disease, such as cancer, leukemia, benzene poisoning or Hodgkin's disease, may eventually cause basophilia and production of stippled cells in the peripheral circulation, as was so well brought out by Johnstone.[7] The difference, however, is that in these conditions anemia appears in a pronounced form long before the stippled cells appear: in the case of frank lead intoxication, stippled cells may be seen long before the anemia appears. This appearance of stippled cells before anemia is, of itself a striking observation and almost diagnostic of lead intoxication. It is not new, as it was emphasized by Cabot in 1904.[8]

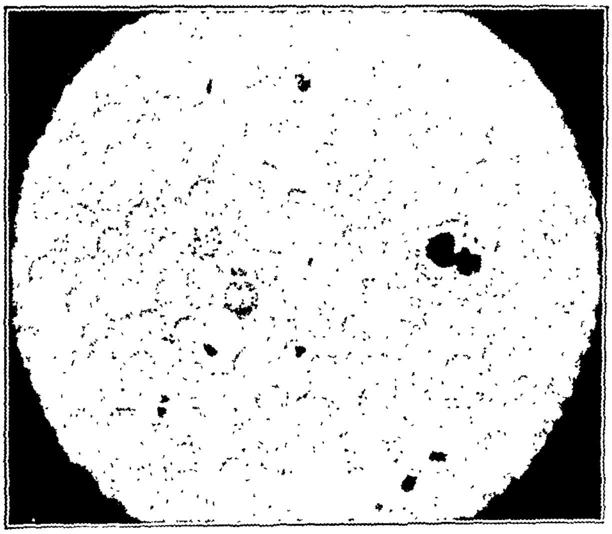

Fig. 3.—The worker showing these stippled cells had three months' heavy exposure to lead before the dangerous level of 20 stippled cells per fifty fields was noted. He had discarded his approved lead dust respirator frequently to smoke. Two weeks after he began to wear a respirator regularly, the number of stippled cells dropped below 20.

So frequent is the association of stippled cells with clinical lead poisoning that the committee on lead poisoning of the American Public Health Association, with Dr. Robert Kehoe as chairman, emphasized it in their report:

> The occurrence of stippling in active lead poisoning is so regular that the failure to find it when one makes use of adequate staining and examination of the blood, should create grave doubt that lead is the agent responsible for an intoxication that is under study.[9]

In the same report, the committee states:

> In a large proportion of cases of lead poisoning, a large increase in the number of stippled erythrocytes in the peripheral circulation occurs in coincidence with the onset of symptoms and perhaps immediately preceding the onset. This abrupt rise above the previous normal level ranges from seven hundred or eight hundred red cells per million up to 35,000 or 40,000 stippled cells per million.

This is the equivalent of a rise from a level of 7 stippled cells, per 50 oil immersion fields to that of approximately 350 per 50 fields.

Any physician who has had experience with clinical lead poisoning knows that the finding of more than 10 to 20 stippled cells per 50 fields in a patient without obvious anemia and with or without a lead line, in the face of known exposure to lead, puts the burden of proof on the examiner who would say that the symptoms were not those of lead poisoning. The characteristic abrupt rise in the number of stippled cells in conjunction with a significant clinical history is practically diagnostic of lead poisoning, according to most of the reports in the literature and the cases in my own experience.[10] Stippled cells, as well as the lead line, have been closely bound up with the clinical history in the diagnosis of lead poisoning for many years. The cells are not difficult to demonstrate, even with Wright's stain, with which every physician is familiar (fig. 3).

Recently, with the growth of more refined methods for study of the urine and blood, there has been a tendency to belittle the time-honored evidence of stippled cells, as well as that of the lead line.

Quantitative Values of Lead in Urine and Blood.—Exact quantitative technics for the determination of lead in the blood and urine are valuable for confirmation in studying the levels of lead absorption. However, they are time-consuming and liable to considerable error when attempted in the average laboratory.

As Fairhall said of the analysis of lead in the body fluids:

> When it is realized that the determination frequently revolves around a matter of millionths of a gram in 1,000 or 2,000 Gm. of fluid or substance and that the total amount of other inorganic constituents accompanying lead in such material may amount to 50 or 100 Gm., it is obvious that the separation and quantitative evaluation of these extremely minute amounts of lead is exceedingly difficult.[11]

[11] Fairhall, L. T.: Analytic Methods in Diagnosis, Occup. Med. 3:13-19 (Jan.) 1947.

I know of no authority who has ever been able to make uncontested the statement that he can diagnose lead poisoning in an individual case from the finding of lead in the urine alone, even if there were 0.3 to 0.5 mg. per liter. He can only say, in such a case, that the person has an abnormal amount of lead in the urine and that this symptom is often seen in groups of workers with lead intoxication. As practicing physicians, we must never forget that the problem of the clinician is the problem of diagnosis of the individual condition of the individual patient. It is not group testing for abnormal levels of lead absorption.

The amounts of lead that may be present in the urine and blood in a so-called normal person, not known to be exposed to lead, are as follows: The upper levels are 0.08 mg. of lead per liter of urine and 0.01 to 0.06 mg. of lead per hundred grams of whole blood. The levels which are safe for an indefinite period in a worker exposed to lead are approximately 0.15 mg. of lead per liter of urine and 0.07 mg. of lead per hundred grams of whole blood. A knowledge of these levels is valuable in estimating safe exposures for groups of lead workers. Figures are available in detail in the report previously referred to:

> The upper limit of normal lead concentration in the urine approximates 0.08 mg. per liter sample and 0.12 mg. for spot samples of 100 cc. Lead in concentration below 0.15 mg. per liter has doubtful significance. Hazardous lead exposure usually induces lead excretion above this figure of 0.15 mg. and the large proportion of cases of lead poisoning examined during an episode of intoxication show urine concentration between 0.15 and 0.30 mg. per liter.[9]

The analysis of lead in the blood requires extremely painstaking and well qualified work by specialized technicians, as the probability of error, both in the collection of samples and in analysis, is very great.

The report continues:

> The normal lead concentrations in the blood range from 0.01 to 0.06 mg. per 100 Gm. of whole blood. . . . Results in excess of 0.07 mg. per 100 Gm. of whole blood are indicative of recent lead exposure, while results in excess of 0.10 mg. per 100 Gm. show that exposure has been considerable.
>
> Mean results of 0.05 mg. of lead per 100 Gm. of whole blood . . . are representative of safe conditions of exposure and are associated with mean urinary concentration of 0.08 mg. per liter with the upper limit of variability for urinary concentration at 0.15 mg. per liter so that the upper limits of safety for the concentration of lead in the blood lie somewhere between 0.05 and 0.07 mg. per 100 Gm. (Page 18.)
>
> In lead colic, the lead content of the blood and urine will be elevated, the concentration in the blood being in excess of 0.07 mg. per 100 Gm. of whole blood and that of the urine will be at least 0.12 mg. per liter (page 51).

In conclusion, Dr. Kehoe's committee stated: "The existence of lead poisoning in a given case is not demonstrated by lead analysis, either on the basis of lead found in the blood, urine or body as a whole." (Page 45.) In other words, no one symptom and no one laboratory observation is diagnostic of lead poisoning.

DIFFERENTIAL DIAGNOSIS

My concern in this paper, however, is not primarily in the determination of safe exposure for groups of lead workers. Certainly one high determination of lead in the blood or urine or the presence of a lead line does not prove anything more than high lead absorption. The differential diagnosis of lead poisoning in an individual case must really be based on wide experience in clinical medicine. The type which is present in about 90 per cent of the patients with clinical lead poisoning which the general practitioner will see and which, therefore, calls for greatest emphasis, is the gastrointestinal type. Hunter, of England, stated that these cases are ten times as frequent as the palsy cases, the second type of lead intoxication.[12] The third type, lead encephalopathy, is rarely seen in modern industry.

Even when confronted with a probable case of lead colic, the physician should systematically rule out other causes for abdominal pain, just as he does in his general practice when faced with the possibility of an acute abdomen. Though many patients have been needlessly operated on for acute appendicitis when the true underlying cause of symptoms was lead intoxication, the converse is just as likely. Unfortunately, the worker who has abdominal pain and is known to be exposed to lead is sometimes immediately treated for lead poisoning, even though he may have an acute abdomen. I have seen this done with fatal results. In any doubtful case of severe abdominal pain in a lead worker, prompt relief from pain with intravenous injection of calcium gluconate is practically diagnostic of lead colic. If calcium given intravenously does not relieve the abdominal colic promptly, one should question whether the colic is due to lead.

One must decide whether abdominal pain is due to acute appendicitis, a perforating peptic ulcer, acute pancreatitis or mesenteric thrombosis. Even an acute condition of the chest has to be considered in any diagnosis of an acute abdomen, so one has to rule out the possibility of pneumonia and acute coronary occlusion.

One practically never sees jaundice in a patient with lead colic unless it is in a far advanced, neglected case in which destruction of the blood has been unusually severe. Then the lead line and stippling of the cells are so pronounced that the true diagnosis of lead intoxication cannot be missed. Hematuria, a common sign with renal colic, is practically never seen in a case of lead intoxication.

In differentiating the violent pain that ensues on intestinal perforation, associated with a peptic ulcer, from the colic of lead poisoning, the diagnosis must rest on a minute history characteristic of ulcer and on the sudden onset of violent pain without letup. This onset is in contrast to the gradually increasing, rhythmic attacks of lead colic, usually associated with almost complete obstipation and with the rapid increase of stippled cells from 10 to 500 or 1,000 per 50 fields. The table emphasizes the following practical points: An increase in stippled cells usually precedes symptoms of lead colic, and the number rises abruptly with the actual onset of disability; the drop in hemoglobin usually occurs a week or two after there has been an increase of stippled cells; stippled cells and lead colic may be present without a lead line, if the teeth are in excellent condition. An acute infection may often be a precipitating factor in acute lead poisoning of the lead colic type.

---

[12] Hunter, D.: Industrial Toxicology, Quart. J. Med. 12: 185-258 (Oct.) 1943.

The pain of acute intestinal obstruction almost exactly mimics the pain of lead colic. In both instances there is constipation, abdominal pain of a rhythmic type and, not uncommonly, vomiting. If there are no stippled cells, however, one must rule out lead colic as a cause of the disabling abdominal pain, even in a patient exposed to lead.

When a physician is called in a case of abdominal colic and learns that the patient is a lead worker, this does not necessarily simplify the problem of differential diagnosis. He meets here a greater challenge to his diagnostic acumen. He must be thoroughly familiar with the perplexing problem of the acute abdomen before he can accurately and safely diagnose acute lead intoxication.

One must remember, finally, that lead workers are just as likely as other persons to have episodes of mesenteric thrombosis, of the rare, acute pancreatitis or of the abdominal manifestations of coronary thrombosis.

Aside from the most common type of true lead intoxication, lead colic, from which the patient usually recovers without residual symptoms in three to six weeks, there do occur cases of true lead palsy, the much rarer, second type of true lead intoxication. As I stated in "Lead Poisoning: Criteria for Diagnosis," mentioned previously:

> They usually show an associated history of preceding neglected lead intoxication of the abdominal colic type, associated with typical lead constipation and characteristic increases in stippled cells. With the onset of the actual palsy, the stippled cell level may not be excessive and often not diagnostic of itself.[10]

* A lead line did not appear previously because of excellent oral hygiene.

† The patient returned to work six weeks later.

It is to be remembered, moreover, that lead neuritis primarily affects the motor, rather than the sensory, nerves and that it involves the extensor muscles, rather than the flexor muscles. This is in contrast to ordinary peripheral neuritis of an infectious or alcoholic type, which is usually associated with violent pain and palsy of both extensor and flexor muscles. The healing period of lead neuritis, or palsy, may extend from two months to two or three years. Even then, any residual disability is rare.

The third type of lead intoxication manifests itself in the stupor or violent delirium of lead encephalopathy, or involve-

> ment of the brain. These cases are in a class by themselves and may not show the warning of previous lead colic or stippled cell rise. Their history is a characteristic story of overwhelming lead exposure seen most dramatically in exposure to tetraethyl lead, with sudden onset of irritability followed in rapid succession by marked excitability, mania, coma, and frequently death. Less dramatic types [sometimes seen in children] are characterized by heavy lead exposure with headache, dizziness, confusion and somnolence as the predominant picture. Such cases, usually marked by convulsions at the onset, . . . are uncommon in modern industry, where we are concerned with adults. With the ordinary precautions now widely used against excessive lead absorption, lead encephalopathy has largely vanished from American industry. There is an interesting observation to be made here, that, even in this most intense type of lead intoxication, . . . providing the [adult] patient has survived the acute stage, after a healing period of disability of two months to two years, there may be no residual effects. In children, however, residual damage is not uncommon.[10]

Whether adult or child is involved, lead encephalopathy is the only type of lead intoxication that kills. However, all these types of lead poisoning are acute, and only these three acute types should be dignified with the term "lead poisoning."

SUMMARY

While I heartily agree with the great value of research in the specialized study of lead absorption, I believe that it is our responsibility also to point out to the general physician that he already has the skills to meet the emergency of diagnosing and treating acute lead poisoning in the individual patient.

In conjunction with the history and physical examination of the patient, including a careful search for a lead line, the study of the blood by determination of the stippled cell curve (usually seen to rise abruptly, in advance of a drop in hemoglobin) is in the majority of cases the deciding point in making a diagnosis of lead intoxication, or frank lead poisoning.

COMMENT

That I am not alone in my insistence on the preeminent importance of these simple clinical observations was shown in a letter I received recently from S. B. Scott, assistant medical officer of one of the largest British companies manufacturing storage batteries, whose 800 workers are exposed to lead absorption. He had written to this country inquiring as to the present status of methods for practical control of lead poisoning. In answer to the reply which I sent him, he states:

> I have been more interested to find that you place more reliance on the methods which we favor here, i. e., routine search for stippled cells and estimation of hemoglobin. Having studied your views, I feel that our present methods are much in agreement and that there is no good reason for changing them.[13]

Certainly, we should emphasize to the nonspecialized member of the American Medical Association, the man in general practice, that the workable technics in which he is already well trained are quite sufficient to make a satisfactory diagnosis of acute lead intoxication and that the differential diagnosis of lead poisoning depends, not on any one laboratory criterion, but primarily on the whole clinical picture.

TREATMENT OF LEAD INTOXICATION

WILLIAM C. WILENTZ, M.D.
Perth Amboy, N. J.

The method of treating the acute phase of lead intoxication has been well established and its rational universally accepted. However, the type of treatment that should be instituted after the subsidence of the acute symptoms is a controversial issue. While the approved treatment of the acute stage will be reviewed, this paper will deal primarily with the theories versus practicability of storing and deleading.

It would seem obvious that the entire therapeutic regimen should be directed toward (1) overcoming the intestinal colic, (2) correcting the anemia, (3) making the patient symptom free with no disability and (4) returning the patient to a remunerative job as soon as possible.

The following procedures are prescribed for the acute stage:

1. Hospitalization or ambulatory, depending on symptoms
2. If hospitalized, bed rest or ambulatory, depending on colic
3. High calcium diet
4. Warm water bag or electric pad for abdominal discomfort
5. One half to 1 ounce (16 to 31 Gm.) magnesium sulfate every morning on arising
6. Antispasmotics, such as tincture belladonna, phenobarbital mixture, every four hours, or amprotropine phosphate (syntropan®) tablets or hydrochloride of diphenylacetyl diethylaminoethanol (trasentine hydrochloride®) and phenobarbital tablets for abdominal discomfort
7. Ten cubic centimeters of 20 per cent calcium gluconogaloctogluconate solution (neo-calglucon®) intravenously every four hours
8. No narcotics advised
9. Complete blood cell count and stippling determination, followed by red blood cell count and stipple cell counts taken every three days
10. Estimation of lead in urine (twenty-four hour specimen) and urinalysis

This routine therapy is predicated on the original contention of Aub[1] and his associates that the direction of the lead stream is similar to that of the calcium stream, that when calcium is being deposited in the bones, circulating lead is being deposited in the bones and that when calcium is being pulled from the bones, some stored lead is also liberated.

Deleading appears to be the method advocated by most authorities, but this does not tell the whole story, because it is unusual to find physicians who actually utilize this procedure: as a matter of fact, recently a questionnaire was sent to twelve actively practicing industrial physicians engaged in this work, and their answers showed that only one physician was using deleading, two physicians formerly used deleading, but had given it up, and the remaining nine had never utilized deleading in any shape or form.

METHODS OF DELEADING ADVOCATED

1. *High Calcium Diet.*—This method was claimed by Lederer and Bing[2] to be the optimum diet for deleading. Taeger[3] arrived at the same conclusion.

---

[3] Taeger, H.: Calcium Therapy of Lead Poisoning, Klin. Wchnschr. **16:** 1613, 1937.

Schilling and Hopper[4] expressed the belief that the use of calcium did not induce superior calcification, but rather had the opposite effect. Gray and Greenfield[5] reported that prolonged high calcium diet and regimen was the best means of deleading. On the other hand, Litzner, Weyrauch and Barth[6] claimed that a high calcium diet reduces lead excretion.

TABLE 1.—*Age Factors*

Total Number Intoxication Cases	62
Age groups	
28 cases between 21-29 years	
22 cases between 30-39 years	
11 cases between 40-47 years	
1 case 54 years	
Average age, intoxication case (years)	31
Average exposure (weeks)	12
Average time lost from work (days)	23
Age of youngest patient (years)	21
Age of oldest patient (years)	54
Exposure of youngest case (weeks)	4
Exposure of oldest case (weeks)	8
Shortest exposure case (days)	12
Longest exposure case (days)	37

2. *High Phosphorus and High Vitamin Diet.*—Gray and Greenfield[5] found the use of an optimal calcium diet with a high phosphorus and high vitamin diet (vitamin D particularly) the best treatment in these cases. Gray,[7] interestingly enough, observed a few years previously that a low calcium and high phosphorus diet (ration 1:4) was ideal in deleading; on the other hand, Lederer and Bing[2] disagreed with this statement and expressed the opinion that the addition of phosphate has no beneficial effect.

3. *Low Calcium Diet.*—As stated previously, Gray[7] recommended a diet low in calcium.

TABLE 2.—*Hospital and Nonhospital Studies*

Total Number Cases 1939-1948	62
Hospital cases	35
Nonhospital cases	27
Hospital Cases	
Average age	33 years (21-54)
Average length of exposure	10 weeks (4-51)
Shortest hospital stay	5 days
Longest hospital stay	31 days
Average hospital stay	14 days
Average loss of time	31 days (7-55)
Nonhospital Cases	
Average age	30 years (21-47)
Average length of exposure	14 weeks (4-28)
Average loss of time	15 days (1-47)

4. *Ascorbic Acid Therapy.*—Holmes, Campbell and Amberg[8] observed much benefit from ascorbic acid therapy in cases of lead intoxication; others have had no success with this form of therapy.

5. *Other Substances.*—Ammonium chloride, potassium iodide (Belknap[9]), sodium bicarbonate, sodium citrate (Kety and Letonoff[10]), parathyroid hormone and 2,3-dimercaptopropanol (BAL) antilewisite have been used.

Do these procedures actually delead? Kehoe[11] stated, ". . . there are grave doubts whether or not the elimination of the toxic agent can be materially accelerated by artificial means" and further added, ". . . this elimination can only be accomplished spontaneously over a considerable length of time." Aub[1] and his associates concluded that complete deleading cannot be done. Oliver[12] and many others have confirmed this observation. It is most interesting that practically all the advocates of deleading admit that the procedure is dangerous and must be attempted only in specific circumstances. Johnstone[13] stated, ". . . this procedure (deleading) has been discarded due to the belief that lead is excreted from the body by normal physiologic processes."

TABLE 3.—*Blood Studies*

Period of Greatest Changes in Counts and Smears—7-14 days after acute symptoms arise		
Period When Blood Cell Counts and Smears Return to Normal (according to whether or not hospitalized)		
Hospital cases		4½ months
Ambulatory cases		5 months
Period When Blood Cell Counts and Smears Return to Normal (according to age)

	(A)	30
Highest count	(H)	300
	(A)	134
Average count	(H)	118
	(A)	75

* (H), hospital cases; (A), ambulatory cases.

It is admitted by its advocates that rapid deleading is to be avoided, and, therefore, it is advisable to immobilize the lead in the bony structure during the acute toxic episode. It is also stated that deleading is then advisable, since the liberation of this store of lead is an obvious factor in the onset of toxic lead episodes during metabolic upsets. It is this latter statement which apparently is the principal argument used by the advocates of deleading. It sounds almost convincing, but in my experience, in treating over 60 patients with lead intoxication and hundreds with absorption, not one patient had any such metabolic upset, liberating stored lead to such a degree as to be incapacitated. I admit that some conditions can produce some free circulating lead into the blood stream, but the results are negligible and the persons are symptom free as far as lead is concerned.

Table 4.—*Disability Studies*

Nonhospital Cases (27)	
Average loss time	15 days (1-47)
Number cases with no loss time	8
Number cases with loss time	19
Number cases with permanent disability award	3
Average award	5% (3-5-7)
Hospital Cases (35)	
Average loss time	31 days (7-55)
Number cases with permanent disability award	4
Average award	7.5 %

Belknap[14] stated, ". . . after an absence from lead exposure of one to two years, lead intoxication practically never develops." Aub[1] stated, ". . . from a theoretical standpoint, deleading is advisable, but from a practical point of view, the answer is dependent on which procedure will advance most promptly to a recovery of health." I agree wholeheartedly with this declaration, but one can hardly miss the implication in this statement that deleading is not advisable from a practical point of view. In other words, it does not appear to be the method of choice.

It has also been stated that circulatory lead may cause tissue damage but stored lead in the bones produces no deleterious effects. If this is so, and, so far as is known, it has been accepted by most men in this work, then what is the justification for employing a method as therapy which is acknowledged by its advocates as dangerous and uncertain as to its ultimate results? No method is available for the complete removal of lead from the body, and I can see no reason for deleading when it is well recognized and accepted that there is a normal metabolism governing the intake and output of lead from the body. It is my opinion that no remedy has been found to justify the dangers inherent in deleading. It is my contention that it is more advisable not to employ deleading procedures, in view of the fact that simple immobilization of lead within the skeletal structures of the body is the most rapid and safe method of bringing about a state of well-being.

My method of treatment during the convalescent (subacute) and chronic phases of this disease is purely symptomatic (associated with observations of the blood). This is simple, direct and productive of excellent results.

In the subacute or convalescent stage, I prescribe as follows:

1. Regular diet
2. Mild laxatives
3. Calcium wafers
4. Iron and vitamin B complex therapy for anemia and as a tonic
5. Monthly red blood cell counts and determination of stippling and hemoglobin
6. No further lead exposure

During the chronic phase, I use the following routine:

1. Permanent removal from exposure
2. Fresh air occupation (yard gang)
3. Adequate diet
4. Multiple vitamin therapy for fatigue, malaise and the like
5. Laxatives for constipation
6. Calcium, oral therapy, if indicated

COMMENT

Intravenous calcium therapy must be continued for at least three to four days after all symptoms of colic have disappeared, and withdrawal must be gradual—otherwise all symptoms may return. Calcium wafers (oral therapy) are given after discontinuance of intravenous therapy. No iron or calcium (oral) should be given during the acute phase, as I do not believe that they can be absorbed and utilized. Vitamins, milk and special diets are acceptable, but their value is questionable.

Permanent removal from lead exposure is obligatory. Hospitalization is preferred in all cases except in cases of mild disease; I believe that calcium should be given intravenously around the clock for quick and best results.

CONCLUSIONS

1. Deleading is not advocated because: (1) it is dangerous, (2) it prolongs hospitalization, (3) it prolongs length of disability and (4) results are uncertain.

Table 5.—*Résumé of Permanent Disability Cases*

Patient	Age, Yr.	Exposure, Weeks	Loss of Time, Days	Days Observed After Acute Phase	Cell Counts Returned to Normal, Months	Disability (Permanent) Award, Percentage
Nonhospital						
A. A.	27	16	12	441	7	7.0
J. A.	25	4	60	60	5	5.0
S. B.	36	20	47	150	2	3.0
Average						5%
Hospital						
E. H.	30	4	30	450	3	7.5
S. W.	40	8	20	87	3	7.5
W. O.	24	32	39	62	3	7.5
J. H.	22	22	22	49	2	7.5
Average						7.5%

2. Calcium immobilization therapy is advocated because: (1) it is simple and safe, (2) it shortens hospitalization, (3) it shortens length of disability and (4) results are certain.

It is therefore my opinion that until such time as some satisfactory deleading procedure is found, which will be simple, safe and able to shorten present length and amount of disability, I shall advocate calcium therapy as the method of choice.

PHYSIOLOGIC EFFECTS OF INDUSTRIAL SOLVENTS

JOHN H. FOULGER, M.D.
Wilmington, Del.

A glance at the stock shelves of any neighborhood store, even in a small town, shows that chemicals are playing an increasingly important part in our daily life. The grocer sells synthetic detergents; the hardware store, paints, laquers, paint and stain removers; the drugstore, insecticide sprays; the corner gasoline station offers window cleaners and all manner of chemicals for service of the automobile, and the local tailor installs modern dry cleaning equipment using the latest synthetic solvents. All of these new materials are intended to simplify or to beautify modern life, and often they actually do so. From the point of view of the physician, however, chemicals may complicate rather than simplify health problems, since, if the materials are not used with adequate information or intelligence, new and unexpected hazards are introduced.

The health hazards, which have so long been regarded as "industrial," are no longer purely such. Manufacturers of chemicals and those who fabricate them into new goods are, of course, confronted with complex problems of health in their workers, and the proper protection of workers by physical means and medical observation is an essential phase of modern industrial organization. Yet the health problems which may arise from the use of the same chemicals in the home or by small business can assume a more serious aspect than the difficulties met in organized industry, for scientific control of exposure to chemicals is not to be expected in a home, nor can it be expected to reach the same efficiency in a small business as in a large plant. It follows that, as the making and using of chemicals increases, so also increases the demand on the general practitioner for at least a working knowledge of their general action. This does not mean that each physician must become a toxicologist. In my opinion chemicals are of minor statistical significance as a primary cause of serious morbidity or mortality, particularly in comparison with the numerous injuries and deaths caused each year by a single physical agent, the automobile. But the entrance of synthetic chemicals into the body can add important physiologic loads to those to which one is already subjected by climate, infectious diseases and physical labor. Such additional loads may assume great significance in the continuing battle with the environment.

USES AND EFFECTS OF SOLVENTS

The present discussion concerns a varied group of chemicals included under the term "solvents." The widespread use of such materials, the mode of application and certain physical properties make them important as a source of health hazards. In industry, solvents facilitate the separation of desired materials from impurities and the final preparation of highly pure products. They are also employed to remove grease and other contaminants from metal. In the household and the small plant, the latter use predominates. In industry, the value of a solvent lies not only in its ability to dissolve required materials but also in its property of being volatile at suitable temperatures so that the dissolved material can be recovered in solid form. Frequently, also, a solvent is chosen because it can be recovered easily by condensation. Solvent recovery systems are highly important, since the loss of the solvent vapor to the atmosphere may be costly. Such systems may be very complicated.

It is this property of volatilization that makes solvents important in any study of health problems due to chemicals. A solid or a liquid remains in its container unless by deliberate interference or carelessness it is dispersed into the atmosphere of a workroom or a home. But a liquid may exert a vapor pressure at its surface at all ordinary temperatures, and the vapor does not stay in one place but may be diffused or be carried by air currents away from the container to all points of a work area or a home. The removal of the vapor at the surface of the liquid leads to further evaporation of the liquid and further addition of vapor to the atmosphere. Special equipment is needed to prevent dispersion of vapors from solvents into the atmosphere, and such equipment is not found in the household and may not be available to the small business user of chemical solvents.

Both the liquid solvent and its vapor can affect the human body, but the relative ease of production of physiologic effects is far greater with the vapor than with the liquid. The surface area of the body of an average man is about 2 square meters. Most of this is usually protected by clothing from easy contact with the liquid, and much of the surface area of the body is not permeated by liquids or vapors with great ease. By contrast, at each inspiration, the lungs offer a capillary surface area of about 100 square meters to the inhaled atmosphere, and through this area inhaled material, if in the state of vapor or gas, is very easily absorbed into the blood stream.

Solvents in contact with the skin may remove natural fats and oils, leaving a dry cracked skin which offers an easy path for infection. If the solvent is in contact with the skin under clothing, so that it cannot evaporate, it will often produce a severe burn, comparable to the ether burn formerly seen so often in open cone anesthesia. For this reason, conclusions as to the ability of solvents to irritate the skin or to cause allergic dermatitis should not be based on "patch tests" in which the liquid is applied to the skin under cover.

Solvents can actually penetrate the skin far more often than is generally believed, entering lymphatic or blood streams and eventually being dispersed throughout the body. The studies of Hudack and McMaster[1] show how easily entrance through the skin can be made by liquids or even solid particles. One can conclude only that the exposed parts of the body are not nearly so well protected by the skin as was formerly supposed.

The greater health hazard from solvents is obviously due to inhalation of their vapors. Materials entering the lungs in low concentration in vapor or gaseous form

This paper and the three preceding papers are part of a symposium of seven papers. The three remaining papers, by Dr. Rex H. Wilson, Dr. L. E. Hamlin and Dr. Nelson P. Anderson, will appear in THE JOURNAL next week.

Read in a Joint Meeting of the Section on General Practice and the Section on Preventive and Industrial Medicine and Public Health at the Ninety-Seventh Annual Session of the American Medical Association, Chicago, June 23, 1948.

[1] Hudack, S. S., and McMaster, P. D.: The Lymphatic Participation in Human Cutaneous Phenomena: A Study of the Minute Lymphatics of the Living Skin (Intracutaneous Injection of Pontamine Sky Blue Dye), J. Exper. Med. 57:751-774 (May) 1933.

can be absorbed into the capillary blood stream to the extent of 75 to 90 per cent of that concentration. The general laws governing such absorption are well described by Henderson and Haggard.[2] The rate of absorption of a vapor or a gas will depend on its concentration in the inhaled air in relation to its concentration and solubility in the blood. So long as the blood passing through the lungs is not saturated with the absorbed material, it can continue to take up more and more. If body tissues can absorb the chemical, they will to that extent diminish the concentration in the blood and so lead to further absorption through the lungs into the blood. Of course, there will eventually approach a time at which the tissues and the blood are saturated, and no more vapor can be absorbed through the lungs. However, before this saturation is reached, there is usually specific action of the chemical, which will drastically change either the respiratory cycle or the flow of blood through the lungs.

Since the absorption of chemicals presented in vapor form to the lungs depends on the exposure of a tremendous area of capillary bed at each inspiration, and on the amount of blood present in the lungs, it is obvious that any situation which leads to increased respiratory exchange or increased blood flow through the lungs will necessarily increase the rate of absorption of the chemical. For this reason, a given concentration of vapor in the atmosphere of the workroom or a home could be harmless to one sitting quietly, but dangerous to that same person performing physical labor, which requires a greater blood flow through the lungs, more frequent oxygenation of that blood flow to satisfy the oxygen demands of the tissues and, therefore, increased respiratory exchange.

Removal from the contaminated atmosphere stops the absorption of vapor through the lungs, and a reverse process of exhalation may then start. The partial pressure of the vapor in blood passing through the lungs becomes greater than that in the alveolar air. The material passes into the alveoli from the blood capillaries and is gradually diluted and washed out of the alveoli by each inspiration of uncontaminated air. The concentration of the chemical in the blood will thus be depleted fairly rapidly. If the tissues, now in contact with blood containing a low concentration of chemical, can give up that which they have absorbed, there may be a progressive and eventually complete removal of the foreign material from all parts of the body. This process may take several hours. Any one who has used ether as a solvent or anesthetic knows that its odor persists in the breath, and its taste in the mouth, for hours after the use is stopped.

Conditions which increase the flow of blood through the lungs or the rate and depth of respiration of uncontaminated air will facilitate removal of the inhaled chemical. But the most easily applied means of doing this—exercise—should be used with great care, for, as shall be seen later, even low concentrations of solvent vapors may affect the arterial and venous circulation and the tonus of skeletal muscles so that the physiologic load produced by muscular activity may be harmful rather than helpful.

The term "solvents" covers a large number of chemical types. One often talks of subgroups as aliphatic or aromatic hydrocarbons, or chlorinated hydrocarbons and so on, with the implication that the specific toxicity of the chemical groups can be so designated. This is a serious error. Because tetrachlorethane and carbon tetrachloride appear to have a pronounced action on the liver, it is wrong to state that, in general, chlorinated hydrocarbons affect the liver. Because benzol produces serious interference with the metabolism of the bone marrow, it is not correct to infer that aromatic hydrocarbons as a group produce such interference. There is no relationship as yet proved between chemical constitution and pharmacologic action, and the more one knows about the ultimate specific pathologic conditions produced in poisoning by modern chemicals, the less one is inclined to argue by analogy from chemical structure.

At the moment, I am not concerned with the ultimate action on specific tissues of inhaled solvent vapors or liquid solvents absorbed through the skin, but rather with the general physiologic effects produced while the blood remains only partially saturated by inhaled vapor and while there has been no appreciable concentration of the chemical in any particular organ or tissue. At this stage a series of symptoms and signs may appear, which is nonspecific for any chemical structure or any physical condition of the chemical. This series of symptoms and signs may be elicited by any chemical which enters the body and is generally distributed through the tissues. The exact mechanism of production of this physiologic picture is not clear. Fundamentally, it is probably due to interference with tissue respiration. Specific differences in chemicals may lead to specific types of interference with factors in the complex process of tissue respiration. Yet, the end result is the same, namely, an insufficient supply of oxygen to the tissues or inability of the tissues to use effectively the oxygen supplied to them.

SYMPTOMS OF INHALATION

The symptoms produced by inhalation of the vapors of solvents include unusual fatigue, lassitude or irritability; headache; gastrointestinal disturbances (nausea, gas on the stomach, loss of appetite, epigastric pain); palpitation; precordial pain; dizziness; pain or numbness or tingling in the extremities, and dyspnea on slight exertion. These symptoms are listed roughly in the order of their appearance as exposure to the vapor becomes more intense or is more prolonged. They are not all necessarily found in one patient, but unusual fatigue is prominent in most cases. Some of these symptoms could be ascribed definitely to the action of the vapor on the central nervous system or its blood supply. Thus, in many cases, the type of headache is that which would be produced by dilation of cerebral blood vessels, and the gastrointestinal disturbance is not due to any particular unpleasant taste or odor of the vapors, but would seem to be due to unusual activity of the autonomic nervous system. The precordial pain could be produced by mere deprivation of oxygen. So also could dizziness and palpitation. Taken as a whole, this group of symptoms (as well as some of the signs observed) is similar to that associated with adrenal cortical insufficiency, but proof is lacking that they are due to this. The gastrointestinal disturbance resulting from exposure to vapors of solvents and leading to loss of appetite and, therefore, to a poor state of nutrition, can build up a vicious cycle. With poor nutrition, fatigue may be increased. So also might dizziness. So long as the exposure to the chemical is continuous or frequently repeated, it might be extremely difficult to find a point of breakage of the cycle.

---

[2] Henderson, Y., and Haggard, H. W.: Noxious Gases and the Principles of Respiration Influencing Their Action, American Chemical Society Monograph Series, New York, Chemical Catalog Company, 1927.

The most easily detectable sign of inhalation of solvent vapor is disclosed by the measurement, under standard conditions, of arterial blood pressure. A low concentration of vapor, just adequate to produce any physiologic response, increases the diastolic pressure without causing a comparable increase in systolic pressure. Frequent repetition or a continuance of this grade of exposure may produce an ever rising diastolic pressure, which may eventually become fixed at levels above 90 mm. I have seen situations in which a solvent at a concentration as low as one-third part per million has produced a diastolic blood pressure of over 100 mm., sitting, in young adults. With a high diastolic pressure but no proportional increase in systolic pressure, there is a chronic low pulse pressure.

Apperly and Cary,[3] after a study of pulse pressure-pulse rate product and the arteriovenous oxygen difference, conclude, ". . . pulse pressure serves as a rough but valuable indication of the reciprocally varying needs and blood supply of the viscera and muscle masses of the body. . . . A high pulse pressure . . . indicates that a larger (and the low pulse pressure of circulatory failure a lower) proportion of the total blood volume is being shunted through the arms (and possibly all muscle masses)." If one accepts this conclusion, a chronic low pulse pressure, without a relative increase in pulse rate, indicates an inadequate supply of oxygen to the muscles. This situation must lead to easy fatigue. If the pulse rate becomes unusually high (e. g., above 100 per minute), acute circulatory collapse can occur, and this can be fatal. Yet, even in such fatal cases, there is absolutely no specific organ pathologic condition detectable at autopsy.

I have never seen systolic hypertension as such produced by exposure to the vapor of a solvent or any other type of chemical, but systolic hypertension can enter the picture if, with a diastolic pressure chronically above 90 mm. as the result of exposure to chemicals, there is added psychic stress, such as financial worry, worry about the family or difficulties in the job.

Inhalation of high concentrations of solvent vapors leads first to a depression of systolic pressure without a fall in diastolic pressure. Again, the pulse pressure is lowered, and, if the situation is allowed to continue, fatigue may result. Increase of the intensity or the duration of exposure may lead to a fall of diastolic pressure with a temporary increase in pulse pressure. Eventually, all three, systolic, pulse pressure and diastolic pressure, are lowered. In persons frequently exposed to volatile chemicals, systolic blood pressures below 100 mm. are common with or without diastolic blood pressure below 60 mm.

When the changes in arterial blood pressure are such as to produce a chronic low pulse pressure and, therefore, a chronic deficiency of oxygen to the muscles, the fatigue and lack of tonus of the musculature, particularly in the abdominal wall and lower part of the body, will result in a low venous return to the right side of the heart. Unless this situation is balanced by an increase in pulse rate, the low venous return may cause an abnormally low cardiac output. With poor venous return and poor cardiac output, there may frequently be extreme dizziness on standing or actual syncope. Recovery from syncope occurs rapidly once the patient falls to the ground, but recovery may not occur if the patient falls in cramped quarters in such a position that the head cannot be lower than, or as low as, the feet.

These signs of abnormal circulation and the unusual fatigue accompanying them may exist for weeks and months. It may be extremely difficult to find their source unless the physician knows that the patient is using volatile chemicals. Patients showing these symptoms and signs may often be considered as suffering from neurocirculatory asthenia or may be classed as subjects for psychosomatic study. As long as the condition exists, the patient may never know what it is to feel really well. Yet, the moment the source of exposure to the chemical causing the condition is discovered and removed, these patients will revert to normal within three weeks to a month, only to regress rapidly if the inhalation of vapor is renewed. It is important to note that a patient incompletely recovered from the circulatory action of one chemical may be extremely susceptible to the physiologic action of a second substance in concentrations which may not have affected the patient previously. Further, the presence in the atmosphere of low concentrations of two or more vapors may lead to an intensity of physiologic action not predictable from consideration of the individual concentrations of the contaminants or even the total of those concentrations.

This simple picture of adverse physiologic trends is not usually accompanied with any indication of specific organ injury. It may be present for weeks or months before the slightest changes could be detected, for example, in the blood picture, if the particular solvent is such as to affect the blood picture. But eventually, unless conditions are remedied, there may be specific organ injury, and a classic picture of poisoning by the particular chemical is observed.

Knowledge gained by frequent observation of the nonspecific phase of physiologic action of chemicals has often tempted me to suggest that the specific organ injury which occurs much later may also be due to local disturbance of circulation. Evidence for this hypothesis is not lacking. Glynn and Himsworth[4] referred to Loeffler and Nordmann, who, using the quartz rod technic for direct observation of the liver in anesthetized animals, observed a sharp narrowing of the hepatic sinusoids in mice and rats within fifteen minutes of inhalation of chloroform. The portal veins remained normally patent. The changes in the sinusoids persisted for several hours. After ten to twenty-four hours, the centrilobular sinusoids dilated, but the blood flow was still retarded. Return to normal took from three to ten days. Wakim and Mann[5] made a similar study. When they momentarily held a swab soaked in carbon tetrachloride to the nose of a rat, there was an immediate, but transient, constriction of liver sinusoids. Rats exposed to carbon tetrachloride vapor for as long as thirty minutes showed a severe and persistent reduction of intralobular circulation. Many sinusoids were obliterated. Most of the sinusoids were still obliterated twenty to twenty-four hours after exposure. Most of those still open were supplied by the hepatic artery. The appearance of the liver and its circulation had returned to normal two to four weeks later. A similar picture followed subcutaneous injection of carbon tetrachloride. Glynn and Himsworth[4] repeated the experiment with carbon tetrachloride and made the same observations. From these studies it would seem possible that even a transient exposure to certain solvents could drastically affect circulation to specific tissues. The ultimate pathologic condition is not necessarily due to direct action of the chemical on the particular tissue showing injury, but to a secondary result of persistently diminished blood supply, i. e., chronic hypoxia. Such a process would make clear the increased susceptibility of the liver to poisons when the patient is suffering from anoxia or malnutrition and the beneficial effects of administration of oxygen or proper diet.

PHYSIOLOGIC ACTION OF SOLVENTS AS CONTRIBUTORY FACTOR

I have already stated my opinion that solvents are not statistically important as a primary cause of serious morbidity or mortaltiy. I would repeat this and amplify it by the opinion that the nonspecific physiologic action of solvents could become an important contributory factor in total morbidity from disease or physical agents. The circulatory deficiencies caused by chemicals render the victim less able to bear other physiologic loads imposed by malnutrition, infection, extreme conditions of temperature and humidity, alcoholism or other addictions, and even conventional therapy with modern synthetic drugs, such as the sulfonamide derivatives. Every one will recognize the list of symptoms which are produced by exposure to volatile solvents as a list common in disease regardless of its origin. There is often no more specificity in the early physiologic trends produced by infection than has been observed with chemicals. Life depends on proper supply of oxygen to the tissues. Two major physiologic systems are concerned with this supply—the respiratory and the cardiovascular. Of these, the cardiovascular is the harder to maintain once it shows serious evidence of failure. Cardiovascular diseases are the primary cause of morbidity and mortality among young and old. The introduction of any new factor which may affect the efficiency of the cardiovascular system must at once assume importance.

FATIGUE

There is a further reason for giving careful attention to the nonspecific phase of physiologic action of chemicals. Impaired circulation results in fatigue. There is a demonstrable relationship between impaired circulation, fatigue and accidents. Accident proneness need not be due, as psychiatrists suggest, to "constitutional inadequacy." It may be due to physiologic inadequacy. A worker (or a housewife), normally careful and, therefore, not often the victim of accidents, may become temporarily accident-prone by injudicious use of a chemical solvent.

COMMENT

The remedy for this situation is, first, education of the manufacturer and vendor of solvents to label them properly, indicating the degree of hazard and the physiologic route, and, second, education of the user to read labels or, if no label is present on the package, to be careful not to spill the solvent on skin or clothing and never to use it in confined spaces or in any situation where there is not good ventilation. Finally, the physician can do much to remedy the situation. In taking the history of a patient, whether in industry or not, he should include details of work performed, use of solvents or special equipment. When no definite evidence of infection or pathologic change is discovered, more details of work performed preceding, or at the time of, onset of illness should be obtained. Last, but by no means least, the physician who fails to discover any ordinary source of the patient's malaise but does obtain some history of exposure to a solvent should not at once conclude that serious poisoning by that particular solvent has occurred. The whole picture of early action of solvents (or other chemicals), in the absence of pathologic changes may be one of general debility, nervousness and apprehension. A definite statement on the part of a physician that such and such a chemical has poisoned the patient will do nothing to allay alarm. It may often introduce a serious psychic factor into the picture—a factor which no amount of subsequent discussion can entirely remove. The better plan is to advise the patient carefully on proper use of the materials involved, to assure him or her that a few weeks without exposure will lead to complete recovery and in the meantime to prescribe adequate rest, proper nutrition and proper, but not excessive, recreation in the open air. If the patient is the operator of a small business using solvents, the physician can do much by advice about hygienic working conditions. Such advice appears much more practical and is deprived of a purely "philosophic" atmosphere by a visit to the place of business, where the physician can observe working conditions and discuss improvements. He will, by such a practice, help both his patient and himself, for only by acquiring a practical knowledge of the use to which modern chemicals are put by the housewife or the small business operator can the physician educate himself in an increasingly important phase of general medical practice.

The Psychopath and Human Misery.—If one could assess the human misery produced, it might well be found that the psychopath has a blacker record than either the neurotic or the psychotic. The neurotic knows he is ill, is only too willing to seek medical aid, and is usually prepared to cooperate; the psychotic's illness is patent to his friends, they can persuade or compel him to receive treatment, and his detention can continue until he is well; with the psychopath, however, it is always the rest of the regiment who are out of step. He has been let down or unfairly treated; it is not he but society which must put itself right; as for seeing or cooperating with the doctor, it is an insult. So the psychopaths in our midst go through life creating trouble. In the factory or office, in the club or society, in the hospital or nurses' home, they build up around themselves a circle of discontent, not the divine discontent of the rebel or reformer, but the narking, carping, querulous complaining of men and women with a grievance against society. I must confess to a fascination in the psychopath, ever since I realized that Hitler and his gang were psychopathic criminals carried to the top on a wave of uncured unemployment. They had all the superficial attraction which makes the psychopath the ideal "con" man. And in Trevor-Roper's book, "The Last Days of Hitler," one can study the miserable spectacle of the psychopath in defeat. One of the problems of politics is to keep psychopaths away from the top; and in Britain we have solved it by making the top comparatively unattractive.—Stephen Taylor, M.D.: The Psychopath in Our Midst, a Danish Solution; *The Lancet,* Jan. 1, 1949.

AUREOMYCIN IN TREATMENT OF EXPERIMENTAL AND HUMAN TULAREMIA

The new antibiotic, aureomycin, first described by Duggar,[1] has been shown to exert specific effect when administered to patients suffering with diseases caused by gram-negative[2] and certain gram-positive organisms.[2b] Detailed reports of its usefulness in rickettsial infections have now been recorded, and aureomycin perhaps exerts its greatest influence in this group of diseases.[3] Favorable results from its employment in lymphogranuloma inguinale have been published.[4] No toxic effects other than nausea and occasional diarrhea attributable to the drug have been observed in our experience or in the patients who have been treated with this agent and reported in the medical literature.

We have been interested in the chemotherapy of tularemia since 1947, when para-aminobenzoic acid (PABA) was observed by us to exert slight benefit in mice experimentally infected with Bacterium tularense. This effect, however, did not in any way approach that achieved with streptomycin, but in infected mice treated with para-aminobenzoic acid survival was prolonged in comparison with untreated controls. Results in a patient observed during the summer of 1948 tended to verify these observations. The patient, a 70 year old Negro, was treated with para-aminobenzoic acid for nine days because he was thought to have Rocky Mountain spotted fever when first observed. He gave a history of tick contact and the absence of demonstrable rash was attributed to the dark color of his skin. The disease was subsequently identified as that of tularemia through the demonstration of agglutinins in rising titer for B. tularense up to 1:10,240. The patient improved with para-aminobenzoic acid therapy with reduction in toxicity and return of temperature to normal in three days. The medication was discontinued after six days of normal temperature. Three days later a febrile relapse occurred, which subsided spontaneously without specific therapy over a period of eight days, and the patient fully recovered.

The role of streptomycin in the treatment of tularemia is well known.[5] Rabbit fever perhaps affords this antibiotic its clearest and most favorable indications for use. Nevertheless, search must continue for other effective agents, since streptomycin is not without certain undesirable side effects, developing particularly after prolonged usage. Smith and his co-workers,[6] in their early work on chloromycetin®, reported in vitro sensitivity of B. tularense to this antibiotic at approximately 0.4 microgram per cubic centimeter.

In experimentally infected mice we have compared the effectiveness of streptomycin, aureomycin and chloromycetin® and recently had the opportunity to treat 3 patients with tularemia with aureomycin. These observations are the basis for this report.

METHODS AND MATERIALS

Mice weighing 20 Gm. were inoculated intraperitoneally with B. tularense in 0.1 cc. amounts of varying dilutions. The strain of tularemia was secured from Dr. Carl Larson of the United States Public Health Service at Bethesda, Md., who had recently isolated the organism from a patient. Stock cultures were grown on blood glucose cystine agar, which produced luxuriant colonies in three to four days. Bacterial suspensions used for inoculations were prepared from these three day agar slants. B. tularense was demonstrated frequently in smears made from the spleens of dying mice and stained by Wayson's technic. B. tularense was recovered by inoculation of material obtained from the exudate of spleens and livers of autopsied or killed animals on blood glucose cystine agar incubated at 37 C.

The antibiotic agents were administered intramuscularly three or four times a day, as follows: streptomycin 0.75 mg., aureomycin 1.0 mg. and chloromycetin® 0.75 mg. per dose. The antibiotic was administered shortly after the infecting dose in most instances, but several groups of mice were treated after eighteen hours. Treatment time ranged from three to four days. In the third animal experiment the infectious inoculum of B. tularense was prepared from the stock agar slant in the dilution of 10 minus 1. A series of six dilutions were then prepared (table 2) in which dilution 6 contained about 3,000 organisms per cubic centimeter.

Aureomycin was supplied by the Lederle Laboratories Division of the American Cyanamid Company and the chloromycetin® by the Department of Clinical Investigation of Parke, Davis & Company.

RESULTS OF EXPERIMENTS WITH MICE

The results of three separate experiments are best shown graphically in tables 1 and 2.

In table 1 it will be noted that all mice, treated and untreated, eventually succumbed to B. tularense infection. In the first experiment the mean hour of death in the aureomycin group was 312, as compared with 36 and 32 hours in the streptomycin and chloromycetin® groups, respectively. The controls died in 23.4 hours. In experiment 2 (table 1), in which the infectious inoculum

was more dilute, the same proportionate results were obtained.

It will be observed in table 2 that there were no fatalities in aureomycin-treated mice inoculated with the fifth and sixth dilutions, whereas in the streptomycin-treated animals deaths occurred in these dilutions. In this latter group, however, the mean day of death was much later than was observed in the untreated control group. In the sixth dilution of the infectious inoculum there were approximately 3,000 organisms (B. tularense) per cubic centimeter.

REPORT OF CASES

Case 1 (fig. 1).—The clinical record of a patient with ulceroglandular tularemia complicated by pneumonia and treated with aureomycin is recorded in detail as follows. The patient was a 53 year old Negro who killed and skinned a rabbit on November 15, the first day of the hunting season. After five days he noticed malaise, cough and fever, for which he received a sulfonamide drug for an unknown period. The temperature ranged between 100 and 105 F., and about four days prior to admission he complained of a tender mass in the right axilla. On admission to the University Hospital, on December 2, he was in a semidelirious toxic state, the temperature was 103.5 F., breathing was quickened, speech was muttering in type and the patient was incoherent. The conjunctivas were moderately injected, and there was inability to protrude the tongue. There was moderate stiffness of the neck with definite limitation of flexion. The blood pressure was 118 systolic and 70 diastolic; the pulse rate was 120 and of poor quality. The heart was not enlarged, and the sounds were normal without arrhythmia. There was suppression of breath sounds in both lungs, elicited best posteriorly, where there were numerous rales heard. There was no sign of pleural fluid. A roentgenogram of the chest taken on admission revealed bilateral pulmonary infiltration. According to Dr. Charles Davidson, there was a homogeneous lobular infiltration present in the left lower lung field overlying the third anterior interspace. There were patchy areas of infiltration in the right cardiodiaphragmatic angle, supradiaphragmatic area and the second, third and fourth anterior interspace on the left. There was gaseous distention of the large bowel.

* The numerator represents the number of surviving mice and the denominator indicates the number of mice used in the experiment.

Abdominal distention was pronounced and appeared to be contributing to the labored respiration. Meningismus was the only abnormal neurologic observation. There was a small fluctuant area on the terminal phalanx of the right index finger from which pus was aspirated. A gland in the right epitrochlear area was peanut sized, and a tender gland in the right axilla was as large as an olive. Material was aspirated from the small ulcer and the epitrochlear gland and blood taken for animal and serologic studies. Sputum could not be obtained because of the extreme degree of dehydration. Intravenous and subcutaneous fluids were administered in liberal quantities and enemas employed to combat the extreme gaseous distention of the intestine.

At 6:30 p. m. on the evening of admission (twelfth day of disease) aureomycin therapy was started, with an initial dose of 100 mg. intramuscularly in buffered solution plus 0.75 Gm. by stomach tube. In the second twenty-four hours 350 mg. intramuscularly and 1.75 Gm. by tube were administered on a four hour schedule. On the third and fourth days 3.0 Gm. and 4.5 Gm., respectively, were given orally every four hours in divided doses. The medicament was then given every six hours in doses of 0.25 Gm. for six days. The total amount of aureomycin administered was 15.25 Gm. orally and 800 mg. intramuscularly.

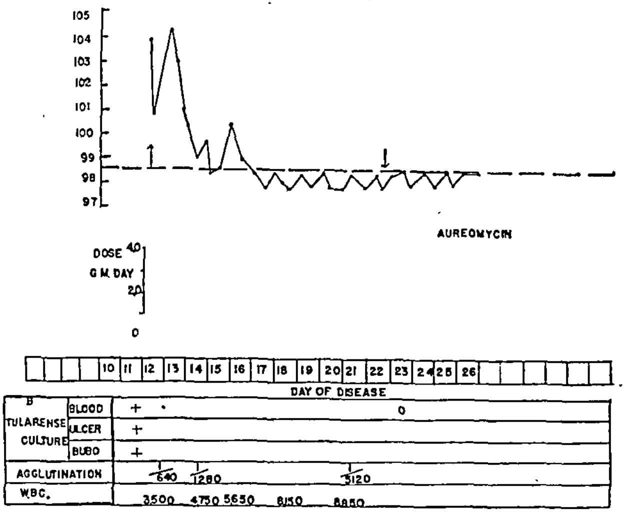

Fig. 1 (case 1).—Chart of results in a patient (male, age 53, 150 pounds [68 Kg.]) with ulceroglandular tularemia complicated by bilateral pneumonia. Treatment was with aureomycin. The upper left hand column of figures shows the temperature (Fahrenheit).

Figure 1 shows the encouraging response. The temperature descended in linear fashion and first reached normal thirty-six hours after institution of therapy. On the following day the temperature rose to 100 F. rectally for a short time and except for one isolated elevation remained normal thereafter. A definite improvement in the mental status was apparent on the evening of the second day, and on the next day (third treatment day) the patient was fully coherent and cooperative. The pulse was of much better quality, although premature auricular contractions were observed. Abdominal distention and discomfort gradually improved and the patient had a formed bowel movement after two days of treatment. The pulmonary signs slowly resolved, and on the ninth treatment day a roentgenogram revealed practically complete clearing of the pulmonary infiltration. The epitrochlear and axillary buboes rapidly resolved, as did the small ulcer on the finger.

Laboratory Data.—The essential laboratory data are recorded in figure 1. Bacteria identified as B. tularense were isolated from the spleens of mice and inguinal glands of guinea pigs, the animals having been previously inoculated with material obtained from the finger lesion, epitrochlear gland and blood of the patient. Organisms were isolated by direct culture from the ulcer and buboes. All strains of B. tularense isolated were agglutinated by antitularemia serum. The agglutinating titer for B. tularense in the patient rose to 1:5,120 (fig. 1).

Studies of hepatic function were performed during convalescence, the results showing no obvious impairment of function of this organ. Results of the thymol turbidity test were negative. The results of the van den Bergh test were 0.3 mg. per hundred cubic centimeters (direct test) and 1.3 mg. per hundred cubic centimeters (indirect test). The serum albumin was 2.87 Gm. per hundred cubic centimeters and serum globulin 2.32 Gm. per hundred cubic centimeters. Convalescence in this patient was rapid, and he was discharged on the sixteenth day after admission.

	BLOOD	0			
AGGLUTINATION				1/40	1/280
W.B.C.		10,100	5,050		

Fig. 2 (case 3).—Chart of results in a patient (female, age 46, 150 pounds [68 Kg.]) with typhoidal type tularemia treated with aureomycin. The upper left hand column of figures shows the temperature (Fahrenheit).

Case 2.—The second patient receiving aureomycin was a 40 year old Negro with typhoidal type tularemia complicated by pleuropneumonia and pleural effusion. Aureomycin, started on the sixth day of illness, was administered orally in 0.5 Gm. doses every four hours. The temperature ranged between 101 and 104 F. on the day treatment was begun and reached normal after three and a half days of therapy (ninth day of illness). Thereafter, until the sixteenth day, single evening elevations of temperature reached between 99.2 and 100.4 F. Clear straw-colored fluid was removed from the pleural space on the fifteenth day which revealed no B. tularense after mouse inoculation. Diagnosis in this patient was confirmed by isolation of B. tularense in mice inoculated with blood and sputum. The serum agglutinating titer for B. tularense rose from 1:80 of the eleventh day to 1:1,280 on the fifteenth day of illness. The total amount of aureomycin administered was 32 Gm. The patient was fully convalescent at the time of writing.

Case 3 (*fig.* 2).—The patient, a 46 year old Negro woman with typhoidal type tularemia, received aureomycin on the eleventh day of illness, with an initial dose of 1 Gm. orally and 0.5 Gm. subsequently every four hours. Toxicity was greatly reduced within twenty-four hours, and the temperature reached normal in forty hours. On the third treatment day there was an afternoon elevation to 101.4 F., but thereafter the temperature remained normal. Recovery was prompt and uneventful. Aureomycin therapy was discontinued after ten treatment days (twenty-first day of illness). The total amount administered was 22 Gm. orally. The diagnosis was confirmed by isolation of B. tularense in mice inoculated with sputum. The serum agglutinating titer for B. tularense rose from 1:40 on the fifteenth day of illness to 1:1,280 on the twenty-fourth day.

COMMENT

In our experience with experimental mouse tularemia, utilizing the standards as detailed previously, we have consistently found aureomycin to be more effective than streptomycin in delaying death. We have observed uniformly that if administration of these antibiotics is stopped in the heavily infected mouse death eventually occurs. Chloromycetin® has prolonged the survival time to a lesser extent than aureomycin or streptomycin. Perhaps frequent administration of chloromycetin[3] in infected mice will improve the experimental results in this animal.

It is well known that the results with the use of streptomycin are highly specific. In an analysis of 56 patients treated in Veterans' Administration hospitals Berson and Harwell[5f] reported that definite clinical improvement was observed within forty-eight hours after institution of therapy with streptomycin and the mean time for normal temperature was seven days. In the article first published on streptomycin by the National Research Council[5a] 67 cases of tularemia were reported, in which there were 63 recoveries and 4 fatalities, and in 55 the results were regarded as striking and immediate. There were 2 cases of relapse in this series. In the experience of others there has been universal prompt clinical response following streptomycin treatment in tularemia.[7] In these cases the temperature returned to normal in periods ranging from two to six days. B. tularense has been observed to disappear from the sputum and pleural fluid soon after administration of streptomycin.[5b] In a review of 6 patients with tularemia, at the University Hospital, treated with streptomycin the average duration of fever after institution of therapy was forty-two hours. In 1 of these patients, who was severely ill with pulmonary involvement, the temperature reached normal in ninety-six hours.

One patient (case 1) reported herein had a severe infection with tularemia which would have probably terminated fatally without chemotherapeutic help. His rapid response to aureomycin with prompt recovery, along with that of the 2 other patients treated with this antibiotic, suggests that this agent may prove as effective as streptomycin in the management of this severe disease. The ease of administration of aureomycin, which may be given with equal effectiveness either orally or intramuscularly, and its freedom from toxic complications justify a thorough clinical comparison with streptomycin in tularemia.

SUMMARY AND CONCLUSIONS

Aureomycin has been found to exert significant beneficial effect in mice experimentally infected with tularemia. Chloromycetin® has demonstrated much less effect in vivo. Three cases of tularemia are reported. The response of the patients to aureomycin therapy is regarded as comparable to streptomycin therapy in degree of effectiveness.

CLOSURE OF TUBERCULOUS PULMONARY CAVITIES

As Accomplished by Residence in the Immobilizing Lung Chamber

ALVAN L. BARACH, M.D.
CHESMORE EASTLAKE Jr., M.D.
JAMES H. CULLEN, M.D.
and
GEORGE FOSTER HERBEN, M.D.
New York

The intention of this paper is to present the use of lung rest, as achieved in the immobilizing lung chamber, as an alternative procedure to bed rest, pneumothorax or thoracoplasty in suitable cases of cavitary pulmonary tuberculosis.

In 1940, residence in the immobilizing lung chamber was shown to provide a normal pulmonary ventilation without discernible motion of the chest or diaphragm and also with disappearance of the voluntary impulse to breathe; it was evident that a degree of lung rest of both lungs and the laryngotracheobronchial tree had been produced which had been impossible of accomplishment with bed rest or other procedures previously used in the treatment of pulmonary tuberculosis.[1] The early encouraging results of this principle of therapy in bilateral advanced disease were then described.[2] Since that time, clinical reports have appeared which indicate that the maintenance of this type of lung rest for a period of four to five months, approximately ten hours daily, resulted in some cases in clearing of exudative lesions and in others in closure of cavities that had resisted other methods of treatment.[3] A follow-up report will be given of 6 of 11 cases of bilateral advanced disease in which arrest of the disease was the consequence of chamber therapy and, in addition, the early observations in a recent consecutive series of 11 patients with chronic pulmonary tuberculosis in 9 of whom closure of cavity with negative sputum took place after a single course of treatment.

The mechanism by which local immobility of the lungs was achieved was the outcome of the development of a method of equalizing the air pressure on both surfaces of the thoracic wall and diaphragm. Alternating positive and negative pressure, 55 to 65 mm. of mercury above and below the atmosphere twenty-five to twenty times a minute, produces a variation in the density of air in a chamber by which ventilation of the lungs of the enclosed patient is achieved. In order to prevent expansion and compression of the chest wall during the initial phases of the positive and negative cycles of pressure, the resistance in the respiratory passageway from the nose to the alveoli had to be accurately and simultaneously counterbalanced.[1b] This was originally accomplished by a chamber within a chamber, but now more simply by a partition around the neck of the patient which is lowered to produce differential pressures between 4 and 8 cm. of water, as required to overcome the tracheobronchial resistance in the individual case. In patients with bronchial asthma, pulmonary emphysema and pulmonary fibrosis, in whom decided narrowing of the bronchial tree has taken place, the relatively rapid compression and expansion of the air entering and leaving the lungs cannot be delayed to the degree necessary to obtain equal pressures inside and outside of the chest and, therefore, to obtain complete arrest of chest movement. During the first week of residence in the equalizing alternating pressure chamber the patient generally learns to renounce all voluntary respiration and from then on resides in the chamber without conscious desire to breathe and with complete arrest of chest movement.

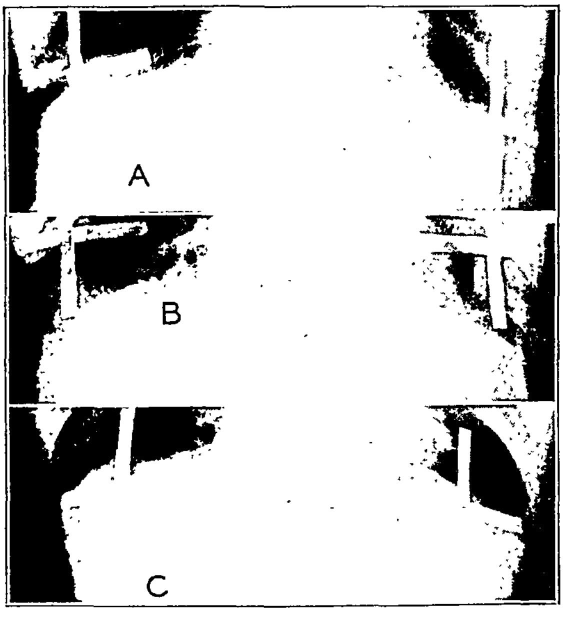

Fig. 1.—*A*, chest movement during quiet breathing revealed by blurring of margins of lead crosses. *B*, degree of chest movement shown by change of position of lead crosses on inspiration and expiration. *C*, absence of chest movement shown by sharp outline of lead crosses during continuous roentgen exposure for ten minutes.

In studies recently carried out, Eastlake and his co-workers[4] have demonstrated the absence of chest movement during residence in the chamber by means of roentgenographic pictures of lead crosses placed on the anterior surface of the thorax. A blurring, or two different positions of the lead crosses, are shown by continuous roentgen exposure on the same film during normal breathing and on two exposures on the same film during inspiration and expiration. However, as seen in figure 1, a ten minute continuous exposure

on a film during residence in the equalizing pressure chamber revealed no blurring of the margins of the lead cross, indicating absence of discernible chest movement.

During residence in the equalizing pressure chamber the patient manifests a form of continuous body rest as well as lung rest, which is impossible of achievement by patients with voluntary respiration at bed rest. The degree of physical and mental relaxation obtained is generally striking. There is also highly suggestive evidence of a decided decrease in the diffusion functions of the lungs, because of the absence of respiratory effort and the diminution in over-all metabolism and oxygen consumption. The pulse rate is diminished 10 to 20 beats per minute, the systolic blood pressure is lowered 10 to 15 mm. of mercury and the temperature in afebrile patients often 1 degree (F.) less during respiration without lung movement. The other side effects of the treatment include an alternating pressure on the ear drum and sinuses, neither of which interferes with the treatment, as these sensations are not found to be disagreeable or uncomfortable after two or three days of residence in the chamber. The morale and cooperation of the patients are generally excellent. After the training period of a week or ten days, no attendant, nurse or technician is necessary, as the patient himself is able to regulate the therapy, opening the chamber and turning off the motor when he comes out for meals.

The summary of the follow-up in the first series of 11 patients with advanced bilateral pulmonary tuberculosis included 6 that obtained clinical arrest of their disease. Two of these patients were lost sight of one year after their discharge. In 1 patient during eleven years of observation, three periods of bed rest for three to four months each were employed for activity in the upper lobe of the right lung. Most of the time, however, during these ten years the patient had been at work. In another case of previously far advanced bilateral disease, the patient was well and at work with consistently normal sputum for four years, when a fall from a stepladder resulted in reactivation of tuberculosis. In 2 other cases of bilateral advanced cavitary tuberculosis, arrest of the disease has continued with the patients at work the greater part of five years in 1 patient and six years in the other, with consistently negative reactions to sputum smears and culture.

In 1 case in which recurrence of cavity took place after lung rest treatment, while the patient was at bed rest in a municipal hospital, a subsequent course of chamber treatment was followed by closure and healing of a large cavity in the upper lobe of the left lung. The reactions to sputum and gastric tests had been invariably negative during the six years prior to reporting. In another case, three courses of therapy were required to effect final closure of cavities in the upper lobes of both lungs. In these 2 patients inhalation of promin® (sodium P,P'-diaminodiphenylsulfane-N,N'-didextrose sulfonate) aerosol were given just prior to cavity closure, during the fourth and last month of treatment. Whether or not promin® had a favorable influence in effecting a more permanent type of cavity healing cannot be determined, but chemotherapy during the final period of shrinkage of the cavity by lung rest therapy deserves study. The response in these patients, and others, clearly demonstrated the specific factor of lung rest in effecting cavity closure, as contrasted to the ineffectiveness of continued bed rest in this type of case.

In a recent series of cavitary pulmonary tuberculosis, in 9 of 11 patients closure of cavity developed, with negative sputum, after a single course of four to five months. The clinical histories of 7 of these patients have been reported by Cullen, Myers, Herben and Barach.[3c] Six patients in the group had been previously treated with pneumothorax, 4 without effective collapse. In 2 cases the cavities had been collapsed by bilateral pneumothorax for five and six years, but reappeared after termination of pneumothorax. Although these cavities had persisted with previous bed rest, closure took place in four months of chamber therapy.

Since it has been demonstrated that tuberculous pulmonary cavities persisting or reappearing after long-continued pneumothorax and bed rest have closed, with the development of negative sputum, the use of the physiologically sound principle of rest to the lungs and the respiratory tract would appear to be amply justified as an additional therapeutic procedure in the treatment of cavitary pulmonary tuberculosis. In 2 patients of the first series tuberculosis of the larynx healed during the first two months' residence in the chamber; chemotherapy was not employed.

Although a new therapy is naturally first tried in cases of advanced disease, it should not be restricted to patients with advanced disease after it has been proved to have no harmful effects and to be therapeutically effective in the majority of patients treated. The use of the lung rest chamber in early cases of exudative and cavitary tuberculosis may also be considered justifiable, especially since it has none of the hazards of collapse therapy and surgical procedures.

Healing in tuberculosis, however, cannot be considered simply a matter of lung rest, since many other factors may continue to make this single agent of little clinical value. In 1 of the cases of far advanced disease, a progressive widespread extension of disease had previously taken place with bed rest, with a rectal temperature at the start of hospitalization of 99 to 100 F. and three months later of 104.5 F. The patient was highly toxic and at the start of treatment was carried into the chamber. Although no cure of the disease was anticipated, the effect of lung rest was a fall in temperature to 101 F. after the first week and decided shrinkage of cavity with clearing of some of the lesions in two months. Immunologic resistance to the tubercle bacillus was lacking, but combined chemotherapy and lung rest therapy may in some cases effect an arrest of disease when neither method alone is adequate. Of the entire group, there were only 2 patients who failed to show some improvement, during a period when defects in the apparatus as well as in clinical and experimental judgment were not infrequent.

The closure of cavity may be seen in two illustrative tomograms, the first case (fig. 2) representing the effect of the second course of lung rest therapy in a patient who had a six year follow-up with negative reactions to gastric and sputum tests and the second case (figs. 3 and 4) the initial closure of a cavity in the midst of an area of fibrosis, in a patient who had had tuberculosis for fifteen years.

The cause of cavity closure is complex and probably variable. Cessation of recurrent inspiratory enlargement of the cavity, which may take place in many cavities during normal breathing, would appear to be a probable advantage of arrest of lung motion. A check valve mechanism undoubtedly operates to maintain cavity in patients with a small bronchial lumen. Elimination of the check valve would appear to be a consequence of maintenance of a constant lung volume.

The answers to a number of questions concerning the use of the immobilizing lung chamber require extensive investigation. These include:

1. What is the optimal number of hours per day in which respiration with constant lung volume, i. e., without chest or diaphragmatic movements, should be maintained? Since ten hours per day accomplishes cavity closure and five hours per day appeared too little, should twelve to eighteen hours be tried?

2. Should chemotherapy be given when cavity closure is imminent?

3. Is closure of cavity by bilateral lung rest in the chamber preferable to (*a*) pneumothorax, (*b*) thoracoplasty and (*c*) routine bed rest?

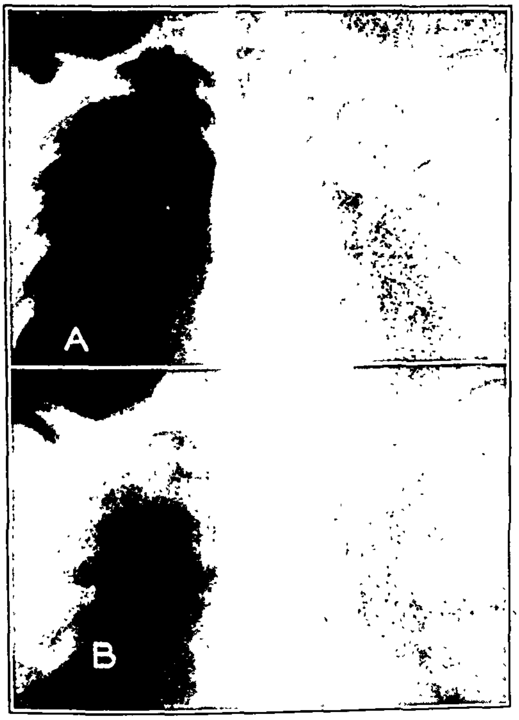

Fig. 2.—Tomograms showing closure of large cavity in upper lobe of left lung after four months of immobilizing lung treatment. *A*, before second treatment. *B*, after second treatment.

4. Are there any disadvantages to trial of total lung rest therapy in chronic pulmonary tuberculosis, and if so what are they?

5. How much bed rest should follow demonstrated closure of cavity after residence in the immobilizing lung chamber?

6. Is relatively slow cycling of the apparatus 16 to 18 times per minute preferable to 20 to 26 times per minute?

7. Should the chamber be used to stabilize doubtful lesions in cases of projected thoracoplasty?

8. Should the chamber be used after thoracoplasty to stop severe paradoxic chest respiration?

COMMENT

The objectives of this paper have been: (1) to present eleven years' experience with a physiologically based therapeutic method of treating chronic pulmonary tuberculosis, a procedure that maintains normal respiration without chest or diaphragmatic motion, with complete surrender of all voluntary breathing, with consequent provision of continuous immobility of both lungs and, finally, a state of lung and body rest during residence in the equalizing pressure chamber not possible of achievement by any other form of tuberculosis therapy; (2) to describe clinical evidence which supports the belief that this procedure exercises a specific effect in accomplishing closure of pulmonary tuberculous cavities, and (3) to suggest that lung rest, i. e., pulmonary ventilation with constant lung volume, be considered not as a measure of last resort in far advanced bilateral advanced pulmonary tuberculosis but as an alternative procedure worthy of trial in cases of less advanced exudative or cavitary tuberculosis instead of pneumothorax, thoracoplasty or bed rest.

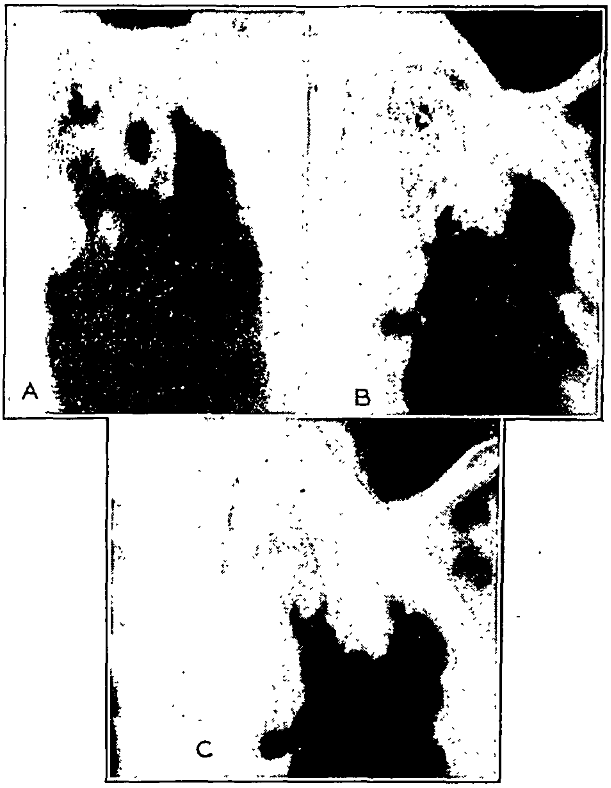

Fig. 3.—Tomograms showing progress in closure of cavity in the upper lobe of the left lung. *A*, before treatment. *B*, after five weeks of treatment. *C*, after fourteen weeks of treatment.

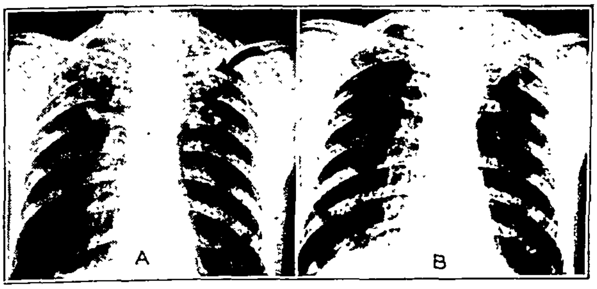

Fig. 4.—*A*, roentgenogram showing cavity in an area of long-standing fibrosis and calcification. *B*, closure of cavity after fourteen weeks of treatment.

In prior publications [5] it was shown that cavities that closed during residence in the immobilizing pressure chamber reappeared in some instances with bed rest and were finally closed during a succeeding course of lung rest therapy in the chamber. The effect of absence of chest motion on cavity closure was shown to be a specific factor and not simply an extension of the period of bed rest. In two previous series of cases of advanced tuberculosis treated at Presbyterian Hospital by residence in an oxygen room with 50 per cent oxygen[6] and in a filtered air room,[7] clinical recovery was not obtained in a single instance, although most of the patients were quite comparable to the patients with advanced disease treated by lung rest therapy in this series.

---

[5] Barach.[3ab]

We are aware that a new departure in the management of chronic pulmonary tuberculosis requires extensive investigation. With the opportunities that have been made available during the past eleven years, two small series of cases have been carefully studied. Pneumothorax had either been impossible of induction or ineffective in obtaining cavity closure, or cavities had appeared after termination of pneumothorax. In some of the recent cases thoracoplasty might have been ultimately employed; in the majority the bilateral nature of the disease made surgical treatment impossible. The clinical recovery that took place in 15 of the 22 cases appeared to be a specific result of lung rest when other measures had been previously shown to be ineffective. Temporary improvement took place in all but 2 of the remaining 7 cases, even in a patient with an evening temperature of 104 F. in whom extensive disease had progressively involved both lungs during bed rest. No evidence of harmful effect was detected.

From the point of view of public health, early detection of pulmonary tuberculosis as well as the use of all available remedies effective in obtaining arrest of the disease seems indicated. Since residence in the immobilizing lung chamber has been shown to result in cavity closure and negative sputum in cases of disease resistant to other methods, this method of treatment merits investigation and trial, from the point of view of preventive medicine as well as the patient himself.

SUMMARY

The effect of the immobilizing lung chamber on closure of pulmonary tuberculous cavities is described. The follow-up results in 6 patients with arrested disease out of 11 treated with bilateral advanced pulmonary tuberculosis are summarized, together with the early results of a recent series in which 9 of 11 patients with tuberculous pulmonary cavity manifested an initial arrest of their disease, with closure of cavity and negative sputum after four to five months' treatment.[8]

The use of lung ventilation without lung movement, i. e., bilateral lung rest, is presented as an alternative procedure that appears worthy of trial in exudative and cavitary tuberculosis instead of bed rest, pneumothorax or thoracoplasty. The use of the immobilizing lung chamber is a feasible and practical method of treatment for patients with chronic pulmonary tuberculosis which has none of the hazards or disadvantages of collapse therapy. The entire operation of the chamber may be conducted by the patient himself without nurse or attendant after the training period of a week or ten days has taken place.

From the point of view of public health, a procedure that results in closure of cavity and negative sputum, when other measures have been admittedly ineffective, would appear to deserve serious consideration and trial in order to have the range of its usefulness determined. A number of questions concerning the use of the chamber, such as the optimal number of hours per day and the over-all length of treatment, the possibility of the joint use of chemotherapy as well as numerous other considerations, merit extensive further investigation.

ABSTRACT OF DISCUSSION

Dr. G. L. Bellis, Winnebago, Wis.: At Sunny View Sanatorium, a public institution for the treatment of tuberculosis, we have been privileged for the past fifteen months to test the therapeutic value of Dr. Barach's lung immobilization chamber. The cases selected for "total lung rest" treatment were of the far advanced bilateral cavitated type, with definitely unfavorable prognosis. With but one chamber at the beginning, it was deemed expedient to divide the twenty-four hour day into periods of four hours, prescribing for each patient either one or two periods, depending on the exigency of the case. An additional chamber, installed four months later, doubled our facilities. Fourteen patients have either completed or are now undergoing lung immobilizing treatment, permitting the following preliminary report to be made: The disease in 3 of the earlier cases, after 1,200 to 1,500 hours of lung immobilization have been given, is now classified as apparently arrested, with the patients taking half-hour walking exercise each day and about ready for discharge from the sanatorium; 3 other patients show persistently normal sputum on microscopic examination and give every promise of recovering; 1 of the group reported on gained sufficient strength in the chamber to undergo a successful pneumonectomy, and another is now awaiting transfer to the general hospital for a lobectomy in order to have a residual tension cavity eliminated. Four of the remaining 6 patients are continuing treatment and show decided symptomatic relief, but too short a time has elapsed to evaluate results, while in 2 patients in the preterminal stage treatment has failed to change the course of the disease. In none of the cases referred to was it necessary to exclude other indicated therapeutic measures. It is perhaps too early and the number of patients treated too few to arrive at definite conclusions. However, based on our observations, I feel that the benefits to be confidently expected from strict bed rest in the treatment of pulmonary tuberculosis are multiplied by use of the lung immobilization chamber. Symptoms of toxemia are promptly brought under control; patients with hemorrhage cease their periodic spills; pleuritic pain is dramatically relieved, and there is, soon after the start of treatment, roentgen evidence of a tendency toward cavity closure—surely a decided advance in results to be obtained in applying the principle of curative rest. Any treatment that will definitely cut down the length of time necessary to secure an arrest of the disease will be a welcome blessing to patients and worthy of the highest praise. Dr. Barach's chamber, in my opinion, possesses that potentiality.

[7] Barach, A. L.: The Use of Filtered-Air Chambers in Pulmonary Tuberculosis, Am. Rev. Tuberc. **27**: 508, 1933.

[8] We wish to emphasize that our use of the term cavity closure does not merely indicate that cavities have been roentgenographically lost to view but that actual closure has taken place as confirmed by bacteriologic findings, by absence of tubercle bacilli in the sputum, and by clinical evidence, ability to work without symptoms. This opinion would appear to be justified in 5 patients who for four years or more after treatment revealed no roentgenologic, bacteriologic or clinical manifestations of cavity, as well as in others observed for two or three years. The disappearance of roentgenographic signs of cavity took place during chamber treatment and not after treatment. The specific effect of lung rest was revealed in some cases by reappearance of cavity on bed rest after chamber treatment and a second disappearance and closure of cavity during a subsequent course of lung rest. When closure of cavity has been manifested for two to four years, collapse therapy is not necessarily indicated on the grounds of greater security, since thoracoplasty itself is not without certain hazards. The expense of the treatment is moderate when chamber cost is calculated on a rental basis, since many patients use a chamber over a period of many years. The electric current expense is nominal and no attendant or nurse is necessary.

PRURITUS ANI et VULVAE

Report of 520 Consecutive Patients with Eczema of the Anal and Vulval Regions

HOWARD HAILEY, M.D.
Atlanta, Ga.

In this report, of a large number of patients, I propose to add further strength to support the apparent fact that pruritus ani et vulvae is a subjective symptom of eczema and not an entity. In two previous published papers on this subject I attempted to emphasize the importance of heredity as a causative factor and the presence of eczema elsewhere, before, during or after an attack of pruritus ani et vulvae as supporting evidence in the diagnosis of eczema of the anal and vulval regions.

It would be foolhardy were I to attempt to influence physicians to discontinue the use of the phrase "pruritus ani et vulvae." This phrase is like the poor, in that it has always been with us and most likely will continue. However, one should not make an entity of a symptom.

Fleeting, occasional itching of any region of the body when unaccompanied with visible cutaneous lesions is not true eczema. Patients who make this complaint are not considered in this report.

The cause of eczema of the vulval, anal and scrotal regions depends on two factors. The first is an indirect cause and is the result of an inherited hypersensitiveness or allergy. The second factor is the direct cause or excitant.

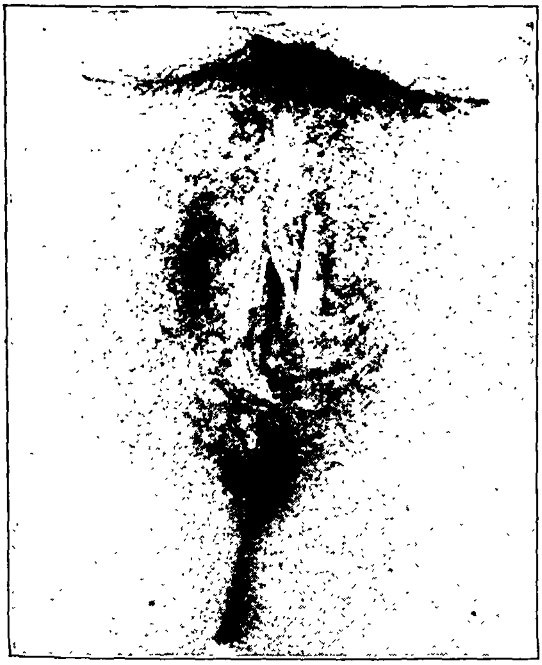

Fig. 1.—Eczema of the vulva, as shown by corrugated infiltrated appearance of the labia.

The indirect cause in the patient may have followed one of the common manifestations of hypersensitiveness other than eczema in one or more close blood relations in either or both parents or their immediate ancestors and side relations. The more commonly associated manifestations of hypersensitiveness are asthma, hay fever, urticaria, migraine, arthritis, sinusitis, pyelitis, cystitis and colitis.

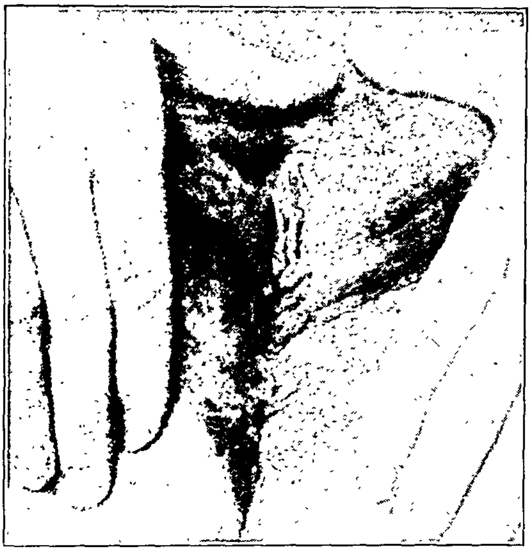

Fig. 2.—Eczema of the vulva and anal region, showing the sodden infiltrated patch on left labia and to the left of the anus.

The direct or excitant cause of an attack may be (1) chemicals (drugs, cosmetics), (2) clothing, (3) hemorrhoids, (4) diet, (5) heat, perspiration and friction, (6) atmospheric conditions or (7) emotions.

Fungous infections have no place in this discussion. An experienced physician will not be confused regarding fungous causation.

Eczema of the vulval and anal regions may attack at any age. The average age of the patients in this series was 43.52 years. The youngest patient was 4 years old. She had severe eczema; also she had eczema elsewhere on the body. Her mother had hay fever, and her maternal grandfather and grandmother had eczema. The oldest patient was 86 years old.

In this series of 520 patients whom I have observed and treated during the eleven year period prior to reporting, there was only 1 Negro (mulatto). She was 64 years old and well past menopause; she did not come from the Atlanta area.

The incidence of "pruritus ani et vulvae" in decades is as follows: Up to 10 years of age there were 2 patients; 10 to 20 years, 9 patients; 20 to 30 years, 69 patients; 30 to 40 years, 145 patients; 40 to 50 years, 116 patients; 50 to 60 years, 110 patients; 60 to 70 years, 50 patients; 70 to 80 years, 17 patients, and 80 to 90 years, 2 patients.

Thirty and three-tenths per cent of the patients had the disease for six months or less, 13.85 per cent six to twelve months, 30.75 per cent one to five years and 25.10 per cent five years or longer.

There have been three instances of mother and daughter with pruritus ani et vulvae being treated at the same time. A number of patients stated in their histories that a sister or mother and sister suffered from the same complaint.

Read before the Section on Dermatology and Syphilology at the Ninety-Seventh Annual Session of the American Medical Association, Chicago, June 25, 1948.

Formerly Associate Clinical Professor of Dermatology, Emory University School of Medicine; Dermatologist, Georgia Baptist Hospital, Crawford W. Long Hospital, Emory University Hospital and Egleston Memorial Hospital for Children; Consulting Dermatologist, Oliver General Hospital, Augusta, Ga.

Several instances occurred in which husband or wife stated that the spouse had the same trouble. Of course, each thought that he or she had contracted the trouble from the other. In this series 342 patients were female and 178 male.

There was a history of one or more manifestations of hypersensitiveness (allergy) in the family in 65.63 per cent of the cases. Here again, this is a high percentage when one considers that many patients did not know their grandparents or even one or both of their parents. So often parents had died before the patient was old enough to make reliable observations. Then too, often the patient was an adopted child—hence the absence of a history of eczema or related manifestations of hypersensitiveness.

In the series, 84.94 per cent of the patients had eczema elsewhere on the body when they presented themselves, or they had had eczema before the attack of "pruritus ani et vulvae."

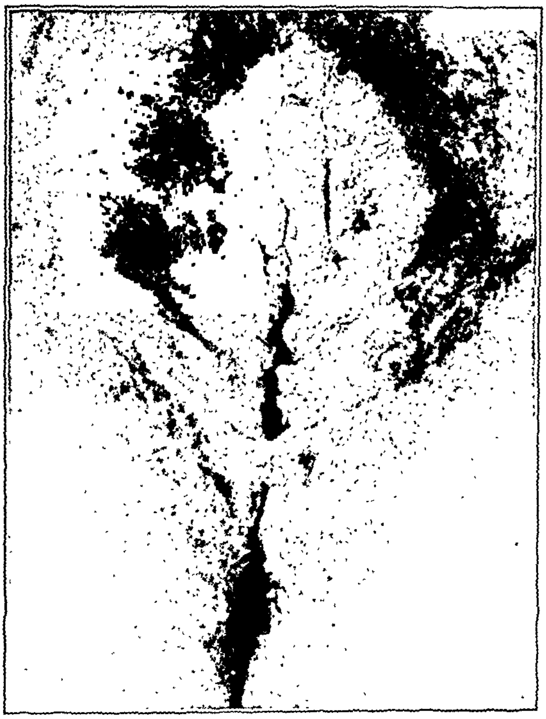

Fig. 3.—Chronic infiltrated eczema with multiple abrasions. The prognosis as to permanent cure is very poor.

Three patients had "pruritus scroti" as well as "pruritus ani."

Eczema of the anatomic parts under discussion have the usual signs and symptoms as eczema elsewhere. The signs and symptoms vary as to whether the attack is acute or a recurring chronic one. Complications in eczema of the regions under discussion are those found with eczema elsewhere. Heat and moisture enter into the initiation of the attack and also delay healing.

The commoner complications are abrasions, fissures, secondary infection and abscesses. Keratoses and occasional epitheliomas follow overirradiation or may appear in the absence of a history of irradiation. Frequently leukoplakia is present. Kraurosis is a name for the end result of long-standing chronic eczema of the vulva and might also well refer to the anal region so affected. When the stage of kraurosis has been reached, the skin has become fibrotic and the skin appendages have disappeared through atrophy.

Insomnia, nervousness and loss of weight are followed by physical exhaustion and mental depression which sometimes becomes serious.

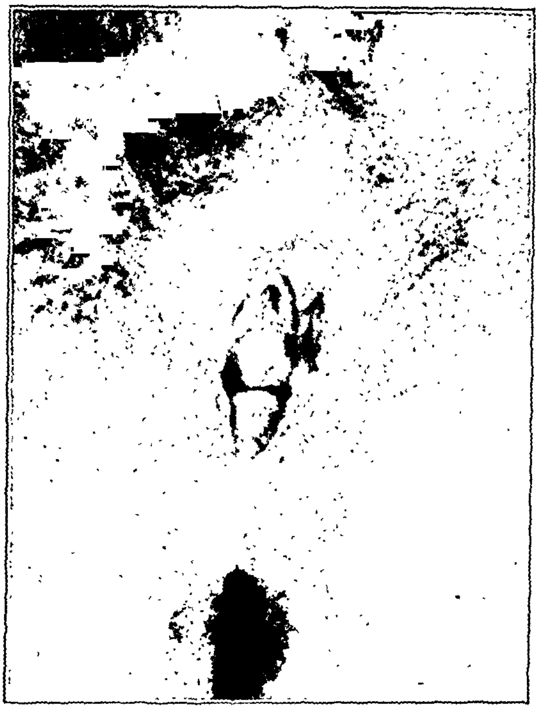

Fig. 4.—Vulvectomy performed on the patient seen in figure 3. This radical procedure failed to effect a cure.

TREATMENT

Surgical treatment is not indicated, but, in fact, is contraindicated in the management of eczema of the anal and vulval regions, except in a limited number of patients who are suffering from concomitant symptoms producing hemorrhoids. Cutaneous tests for allergy have no legitimate place in the diagnosis and treatment of eczema, and the practice will probably be discontinued in the near future.

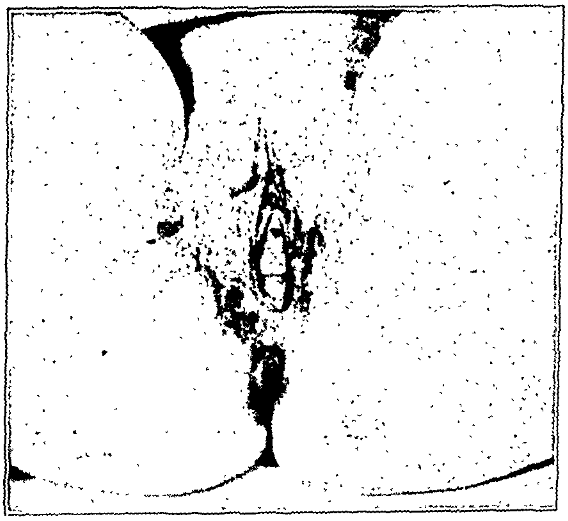

Fig. 5.—This illustrates overirradiation. Atrophy, loss of hair, telangiectases, keratoses and epithelioma followed.

Periods of rest and even complete rest in bed are necessary to give relief to some patients. Frequently sedation is indicated. A change of environment is desirable when the patient is at odds with one or more other members of the family. Cold damp compresses are indicated in the acute stage of eczema. Ointments usually aggravate instead of alleviate the condition. Advice as to the clothing and withdrawal of cosmetics —powder, perfume and especially nail polish—are among the important details in the successful management of eczema of the anal and vulval regions.

Saline douches are of great value. A cold quartz lamp is valuable in treatment. Roentgen therapy continues to be the best single treatment in the quick relief and cure in the majority of patients with this condition. The physician who administers roentgen rays should be well trained. The physician who gives roentgen treatment in a careless way must expect trouble sooner or later. No roentgen rays should be administered to a patient who has previously had treatment until a record of the treatment has been obtained. Roentgen rays properly given are of no danger to the sex organs. However, some physicians will continue to use a tampon and deny the patient the benefits of roentgen treatment. Ill advice to the effect that roentgen rays will damage her organs, cause sterilization and prevent pregnancy temporarily pacifies the patient until the nervous tension drives her to seek help elsewhere.

SUMMARY AND CONCLUSION

A study of 520 patients under treatment for pruritus ani et vulvae during the eleven year period prior to reporting convinced me that all of them had or have eczema. The cause of eczema is twofold, namely, an indirect cause provided by heredity and a direct cause provided by some excitant from without or within the body. The presence of bacteria, yeasts, fungi and amebae in the vagina and at the anal skin juncture are practically always saprophytic and not pathogenic as related to eczema. So-called cutaneous tests for allergy have no place in the management of eczema.

Atlanta, Ga., has a Negro population of approximately 120,000, but I have not seen a single Negro patient from the area with eczema of the anal and vulval regions.

Approximately 66 per cent of this series were female and 34 per cent were male. There were 65.63 per cent who gave a history of one or more manifestations of hypersensitiveness (allergy) in the family and 84.94 per cent who had eczema elsewhere on the body on their first visit or had had eczema elsewhere prior to the attack of "pruritus ani et vulvae."

A study of the incidence of the disease indicates that the menopausal period is not a dominating factor. The decade incidence does indicate that eczema of the anal and vulval regions is commonest during the active working period of the patient's life. Recurrences and relapses are common, but if the patient cooperates and strict attention is paid to the details of treatment, relief and clinical cures for periods of years may be expected in the vast majority of patients suffering from "pruritus ani et vulvae" or eczema of the anal and vulval regions.

478 Peachtree Street N. E.

ABSTRACT OF DISCUSSION

Dr. G. A. Grant Peterkin, Edinburgh, Scotland: I will mention first the points with which I disagree. I cannot subscribe, for instance, to the view that pruritus ani et vulvae is merely a form of eczema, although eczematous changes are frequently present. The name pruritus means merely itching, and itching of the anal and vulvar regions may be produced by a vast variety of causes. In 107 cases in 1946 referred to me as cases of pruritus ani et vulvae there were such different conditions as psoriasis, condylomata acuminata, condylomata lata, carcinoma cutis, lichen planus, amoebiasis, prurigo nodularis and tuberculous sinuses. Also, there are persons suffering from severe pruritus ani et vulvae in whom no cutaneous changes are apparent but in whom this intense itching has been present over a prolonged period. Certainly the skin of most patients shows an eczematous reaction, but this reaction may be due to many different causes, such as atopic dermatitis, infectious eczematoid dermatitis, flexural seborrheic dermatitis and fungous infections, either tinea or infection due to Candida albicans, which may be easy enough to diagnose but which may, on the other hand, offer great difficulties in diagnosis. I consider the role of the gynecologist most important and frequently obtain the benefit of his advice, as cervicitis and trichomonal infection may be present and the yeast organisms may also attack the vagina. Dr. Hailey mentioned that approximately 66 per cent of his series were women and 34 per cent men. In my small series of 107 cases, 67.3 per cent were women and 32.7 per cent men—a similar figure. Like Dr. Hailey, I was somewhat surprised to find that in my cases the age group with the highest incidence was that between 30 and 40 years of age, as one somehow tends to believe that pruritus ani et vulvae is most frequently seen in persons past middle age. However, it is possible that many women over 40 seek advice from the gynecologist rather than the dermatologist. Finally, I make a plea even more compelling than Dr. Hailey's against the indiscriminate use of roentgen rays in this condition. All dermatologists know how effective this therapy is in the average case, but one should first make every effort to discover the exact cause of the itching, e. g., contact eczema due to medicated toilet paper and purgatives, before commencing it. One should bear in mind the lot of persons suffering from both the pruritus and radiodermatitis. Starch poultices will usually tide the patient over a crisis better than roentgen rays, while for patients with the unfortunate combination of radiodermatitis and pruritus, I do not know a better treatment agent than thorium X.

Dr. James Herbert Mitchell, Chicago: I find it impossible to generalize about pruritus ani et vulvae. First of all, one must make all kinds of investigation in order to determine what the causative agent is. Failing to find anything, one has only an itching that is an irritation of the nerve endings of the region. During the war, I had a tremendous increase in cases involving war mothers and war brides. It is the number one problem in the private practice of dermatology. All sorts of things must be looked for, and I do not agree with Dr. Hailey, in the least, about the patch test. Also, Dr. Peterkin has called attention to the fact that it is very necessary to make cultures and to exhaust the possibilities of investigation. A number of years ago, I published an article in The Journal on the production of pruritus and dermatitis ani by anusol® (a mixture of bismuth oxyiodide and resorcinol sulfonate in a fatty base) suppositories. There is a strong reaction in persons who are sensitized to resorcinol. A case that occurred in my practice some years ago was that of a woman of 35, previously divorced, who had been married for three months and had been having a good deal of trouble in the vulval region. The region was stained with Gibson's picrate ointment. She had been in the hands of a very competent colleague and had been given patch tests to all the medicaments, the reactions to which were negative. Eventually I found that her husband, a veterinarian, had been using an ointment on his hands each night for three months. Patch testing with this ointment gave a violent reaction.

Dr. Stephen Rothman, Chicago: What has been said about hereditary influences seems important in the interpretation of pruritus ani et vulvae. It appears that it is a particular genetically induced state which makes a person an "atopic" or a "neurodermatitis" type. There are certain attendant somatic and psychic stigmas. Among the somatic stigmas are the susceptibility to itch stimuli, the great tendency to lichenification in response to scratching and multiple dermal sensitivities. I agree with Dr. Hailey that the sensitivities never have been proved to have any etiologic significance. A study of the material of the University of Chicago Clinics was published in *Gastroenterology* in September 1945. Fifty-five per cent of 70 patients with pruritus ani were atopic, whereas the remaining 45 per cent did not have lichenification, and the perpetuation of the itching-scratching circle had a different mechanism than in atopic persons. In both forms banal external irritation, such as the cleansing with toilet paper, caused the onset of itching spells and contributed greatly to the persistence of the condition. The most important point in the reform of the hygiene of the anus has been the avoidance of rubbing, the rubbing being defined, as I explain to my patients, as a "round trip movement of the hand." This could be best achieved by sitz baths and drying by patting. In addition to measures directed toward avoidance of external itch stimuli, one can successfully decrease the state of itching hyperexcitability by measures acting both on the central nervous system and on the periphery. The combined treatment method, as outlined in the paper previously mentioned, was successful in 93 per cent of the 50 patients on whom a follow-up could be made.

Dr. Adolph Rostenberg Jr., Chicago: I agree with the speakers that pruritus ani et vulvae is an important clinical problem. However, I feel, as does Dr. Peterkin, that one must make an assiduous search for the specific cause in a given case. It seems to me that one will not make much progress if one labels all these conditions, as Dr. Hailey apparently has done, eczemas. Eczema, to me, is a morphologic reaction pattern which can arise from a myriad of causes, and knowledge is not gained by one's calling the conditions eczemas. A word as to kraurosis. If I understood Dr. Hailey correctly, he said that some cases of kraurosis arise on the basis of an eczema. It is difficult for me to believe this, as kraurosis is an atrophic condition. There is considerable evidence that it is or stems from lichen sclerosus et atrophicus. It seems to me that the reason for the sex distribution, two-thirds female and one-third male, is obvious; after all, the title of the paper is "Pruritus Ani et Vulvae."

Dr. Howard Hailey, Atlanta, Ga.: I sent a copy of my paper prior to this meeting to Dr. Peterkin and to Dr. Mitchell, and, from their discussion, apparently they did not read the paper. The causes of itching of the vulva and perianal region were purposely not included in this paper. If anyone gained the impression that I was condemning patch testing as an aid in diagnosis, I am sorry. I am strongly in favor of patch testing. I know that Dr. Mitchell finds patch tests most valuable. I read a paper on eczema, eczema of the vulval and anal regions, 3 cases in the scrotal region, and I tried to emphasize that contact dermatitis, intertrigo (diabetes, etc.), fungous infections, pinworms and the like were not considered in this paper. It is hoped that only eczema and eczema with complications will be kept in mind so far as this presentation is concerned.

Hodgkin's Disease and Tuberculosis.—In spite of repeated attempts to connect Hodgkin's disease etiologically with some form of tuberculosis, all efforts have failed and there remain but two interesting correlations. One is the often chronic inflammatory granulomatous appearance of the lesions of Hodgkin's disease, and the second is the consistently high percentage of negative tuberculin reactions in patients having Hodgkin's disease. . . . A low incidence of positive reactions to tuberculin tests also may occur with other diseases of the reticuloendothelial system (such as leukemias and lymphosarcoma) which may be caused by that system being "blocked out," with resultant anergy. . . .—Warren L. Bostick, Hodgkin's Disease, *California Medicine*, February 1949.

HAIR AND SCALP TREATMENTS AND PREPARATIONS

A Report from the Committee on Cosmetics

Note.—The Committee on Cosmetics was established by the American Medical Association to study cosmetics as they are sold to the American people. The Committee examines the claims made for various preparations and determines the safety or harmfulness of cosmetics. The information accumulated is made available from time to time in reports to the public and to the medical profession, depending on the nature of the report and the technical information that it contains. These informative articles will be made available through the Association's publications such as *Hygeia* and The Journal of the American Medical Association.

The Committee also has undertaken an evaluation program which will permit the use of a Committee seal for cosmetics that meet the rules of the Committee. This program is similar to others undertaken by the American Medical Association in relation to drugs, foods and devices.—Editor.

Even the Federal Food, Drug and Cosmetic Act cannot protect credulous persons against extravagant and deceptive claims for hair preparations. Clever advertising maneuvers circumvent the law and imply results which are impossible.

HAIR AND SCALP TREATMENTS

Every business area has one or more offices devoted to hair and scalp treatments by persons self designated as "hair experts," "hair and scalp specialists" or "trichologists." Their business is to convince the public by various approaches that their "proved," "exclusive" or "specialized" method can prevent or cure baldness.

The advertising of these hair and scalp establishments assumes a characteristic pattern. They deal with a condition which the public has associated with health and the medical profession; they assume a professional aura which, in turn, is used to justify their so-called professional fees. The public is invited to have a "consultation," a free "scalp examination" and a "diagnosis" by a "hair expert," "specialist" or "trichologist." In fact, one firm has simply and glibly solved the problem of the cause of baldness by stating that it is due to fourteen local causes. They offer to diagnose, in a brief scalp examination, which of the fourteen is responsible for the loss of hair.

To the average nonprofessional person, these high sounding terms have a medical tang and connote scientific background and training. These self-promoted authorities are not physicians and, so far as can be determined, have no qualifications other than a full head of hair, a business brain and an appetite for easy money.

Fees in amounts equivalent to that of a major surgical operation are paid by thousands of persons yearly for futile hair-saving or dandruff-curing treatments or remedies. "The Thomas'" claim that their forty-five offices manned by the "World's Leading Hair Experts" treat an average of 1,800 persons each day, or on this basis, 640,800 persons a year. At $6 to $10 a visit, this concern has a yearly income of approximately $3,844,800.

Typical of those persons contributing to the financial success of these firms is a patron who wrote that after thirty treatments for a promised dandruff cure at a

$200 fee, he was advised that failure was due to too few treatments. Another stated that he had enrolled for a course of forty to sixty treatments to stimulate hair growth, paying in advance, thereby taking advantage of a liberal cash discount. At the end of the sixtieth treatment he was told by the "trichologist" that he needed additional treatments to further the progress already made and that if added treatments were not taken some of the gains already made might be lost. A complaint to the central office brought the reply that like physicians they were unable to predict the number of treatments necessary or the reaction of the client's scalp. Therefore, after an expenditure of $450 for treatments and take-home products, the writer indicated that his hair and scalp were in little better condition.

The methods uniformly fall into familiar patterns; rarely do they show originality in the approach. The preparations which they promote have the usual hair "tonic" formulas, which consist essentially of either an antiseptic, an irritant or a keratolytic substance.

Massage.—The hair "tonics" are usually applied with massage, which is claimed to increase the circulation, thereby stimulating cell activity and, consequently, favorably influencing the growth of hair. There is no proof that the temporary increase in blood supply to the area massaged postpones the loss of hair or in any other way influences baldness. One firm suggests the massaging of only certain areas of the scalp, supposedly at those sites where the larger blood vessels enter the scalp. Another suggests massaging with the head lower than the waist. In addition to the fact that there is no scientific basis for these theories, over a period of years actual use has proved their worthlessness.

Other firms employ mechanical devices such as electric brushes, vibrators or a suction apparatus for the purpose of increasing circulation. The failures are the same as with manual massage.

In rare instances, continued massage may produce a fine colorless fuzzy down similar to that seen on the heads of some newborn babies. Alert firms are quick to capitalize on this fact by advising their patrons to observe the condition of their scalps under a bright light for the presence of this fuzz on the theory that this is the beginning of a real growth of hair. This fuzz cannot be considered either in length or appearance to be a real growth of hair or a precursor. Frequently, after reaching a length of about ½ inch (1.27 cm.) the fuzz drops off and is not replaced. In any event, its appearance is without cosmetic value, since it is invisible except on close well lighted inspection.

Ultraviolet Rays.—No matter how illogical or unscientific the basic principles, any new treatment which has public appeal and which has any degree of practicality will eventually be tried in the treatment of baldness. Therefore, ultraviolet lamps enjoy some popularity. In trained hands, ultraviolet rays have some usefulness, but only those whose scientific background makes them capable of understanding the limited available data and the potential health hazards should undertake the supervision of such treatments.

Mail Order Hair and Scalp Treatments.—Mail order businesses function by sending directions at regular intervals through the mails; the client carries out the treatment himself. Invariably, some solution or ointment is involved as well as massage of various forms. One under the name "Laboratories" offers to diagnose scalp conditions by microscopic examination of a few strands of hair sent through the mail. Although certain physical characteristics of the hair can be observed with a microscope, such as whether or not it is human, or dyed, or permanent waved, or contaminated with foreign matter, the physiologic condition of the scalp cannot be determined by such examinations.

HAIR "TONICS"

Drug and department stores enjoy gratifying sales of alleged hair "tonics," a term used here simply because the preparations to be discussed are on the market under this name. However, hair "tonics" is misleading since the term "tonic" has a definite meaning to the average person. The word is associated with something that is conducive to a healthy condition or to overcome a diseased condition. However, the so-called hair "tonics" simply groom the hair.

There are no magic or mysterious ingredients in these preparations. They usually consist of simple mixtures of well known drugs. Apparently, the majority of conventional products have similar basic formulas, although an attempt is often made to suggest that they contain a miracle-performing complex chemical. Among the common ingredients used are acetic acid, resorcinol compounds, salicylic acid, mercuric chloride, sulfur and betanaphthol. The chemical and pharmacologic properties of each of these drugs are well known. With these data in mind, resourceful manufacturers conjure a makeshift adjustment between the pharmacology of these ingredients and pseudoscientific facts about baldness and dandruff. The past history of each of these chemicals after repeated use in many hair preparations indicates that they are ineffective in growing or maintaining hair or in curing dandruff. Disappointment and futile expenditure of money will result from the use of hair "tonics" for these purposes, and the possibility that certain of the ingredients may cause a severe dermatitis is ever present.

Sulfonamide Drugs in Hair "Tonics".—As soon as a drug is generally accepted by the public as a cure-all, it will appear in a hair or scalp preparation. Therefore, the sulfonamide compounds are used rather widely for this purpose, in spite of the fact that intensive clinical and laboratory research records the worthlessness of these drugs in hair preparations.

Furthermore, serious dangers are involved in the indiscriminate use of these chemotherapeutic agents. A sensitivity may develop which will not only result in a dermatitis of varying degrees of severity, but also may preclude the future use of the drug should the person require it. In addition, small repeated applications of the sulfonamide compounds may enable organisms present at that time to develop a resistance to the drug, and any future infection caused by this resistant or drug-fast strain of organisms cannot be effectively treated with this particular drug. Chemotherapeutic agents should, in all instances, be used only under the supervision of a physician.

Hormones in Hair "Tonics".—For similar unsound reasons, hormones, which have also been widely accepted by the public as cure-alls, are found in some brands of hair "tonics." Evidence is lacking that hormones applied in any form to the scalp will influence the growth of hair in ordinary baldness.

True, there is some association between hormones and the normal amount and distribution of although its exact nature has not been definitely established. Under no circumstance should hormone therapy be used unless definite evidence of a hormone dysfunction prevails. Such dysfunction is not diagnosed solely on the basis that the person has lost or is losing his hair. Because the hazardous potentialities of hormones are still not completely determined and, in particular, the effects of frequent small amounts not definite, the topical use of hormones in cosmetics is to be condemned. Hormones are absorbed through the skin and, in large enough amounts, can cause systemic changes.

Vitamins in Hair "Tonics."—Vitamins do not influence ordinary baldness. A newspaper report recently stated that a foreign university had conducted studies on the injection of vitamin B into the scalp in cases of baldness, with some success. Scientific reports in this regard are lacking.

Charlatans invariably recognize the potentialities of newspaper statements of this type, regardless of source or authenticity, and make them the basis of a business venture. Injections of this nature into the scalp can have disastrous results.

In fact, the injection of any substance into the scalp is a highly questionable and risky procedure, since the amounts of subcutaneous fat and the thickness of the muscular layers are not conducive to absorption of a foreign substance. In addition, only substances of carefully controlled sterility and physical characteristics can, with any degree of safety, be injected.

Hair "Tonic" Advertising.—The advertising of hair "tonics" makes a concerted effort to create a "bald" conscious public. The tenor of advertising revolves about the cause, control and cure of baldness with such picturesque language as "growth-choking dandruff," "strangled hair follicles" and "dandruff is Nature's warning signal." In some instances, the advertising claims are so blatantly misleading and false that the Federal Trade Commission initiates action. In the interim, a period of time may elapse which will allow a considerable fortune to be amassed by the manufacturer, who can then nonchalantly view any government action which removes his products from the market. The disgruntled and defrauded public then views the entire cosmetics industry with suspicion and distrust.

The germ theory of dandruff is popular and is adroitly adjusted to the use of antiseptics in hair "tonics." For some time, people were rinsing their mouths with a hair "tonic," since listerine® offered the same formula for its mouth wash and its hair "tonic." The term "antiseptic" is a good selling word, because it connotes to the average reader a protection against germs in general. Until such time as an organism is proved to be the cause of so-called dandruff and until such time as a drug is found which kills or inhibits that specific organism, this type of advertising is supported only by supposition.

A second theory of considerable sales appeal suggests that itchy scalp leads to dandruff which in turn is a precursor of baldness. The physiology of itching indicates that both functional and organic causes must be considered. Functional pruritus, in which there are no visible changes on the scalp, is a fairly common affliction. When attention is concentrated on the scalp during periods of inactivity, fatigue or tenseness, minimal pruritus becomes noticeable. In addition, the repeated use of drying shampoos may lead to more apparent flaking of the skin and itching which is temporarily relieved by shampooing. In those instances in which there is definite scalp disease of which itching is a symptom (not a cause) diagnosis and treatment should be relegated to a physician.

A third popular theory proposes that the use of irritants or massage increases the blood supply to the part, thereby accelerating cell activity and, concomitantly, hair growth. There is no evidence that the temporary increase in the blood supply rendered by massage or by an irritant chemical will in any way influence the course of baldness. If there were any proved basis for this theory, the blood supply can be increased simply and safely by temporarily lowering the head below the waist. Unfortunately, the chemicals used as rubefacients can cause sensitization, and their indiscriminate use may increase rather than decrease so-called dandruff.

Testimonials.—The advertising of hair "tonics" and hair and scalp treatments abounds in testimonials accompanied by "before" and "after" pictures. These statements testifying to miraculous results obtained from the use of a certain hair preparation must be viewed critically. The processes of the human body are so complex that the average person is unable to distinguish between results which are due to natural causes and those due to artificial remedies.

Testimonials can be obtained in several ways. They can be bought outright; they can be faked; often they are genuine from the documentary standpoint and have been written in good faith. These letters are usually volunteered by well meaning persons who have absolutely no knowledge of the nature of the challenging problems of the loss of hair. Most courts of law are cognizant of the limitations of the lay public in medical matters and their testimony is not accepted as evidence.

Widely used are "before" and "after" pictures showing a person with varying degrees of baldness originally, and the same person with more hair following the use of certain brands of hair "tonics." In some instances, hair grows on a previously hairless head, but not as a result of any external application or treatment. For example, about three months after prolonged febrile illnesses, severe nervous shocks or traumatic injuries, scalp hair may fall out completely or a rapid general thinning of the hair may take place. At other times, the hair falls out in patches known as "alopecia areata," or the entire head and orbital areas are left without hair. These instances can be differentiated from ordinary baldness by the lack of characteristic patterning which occurs in the latter, first in an area above each eye and at the vertex of the head; both areas eventually merge, but hair will remain at the periphery so that, regardless of the extent of baldness, regular hair cuts are still necessary.

In symptomatic loss of hair, to resort to hair "tonics" and "professional" hair and scalp treatments is unnecessary. Regrowth usually takes place due to the forces of nature and not to any external application. The human mind is so constituted that one is much more prone to give credit to artificial measures than to nature and will, through misdirected gratitude, allow testimonials to be published.

Guarantees.—These hair "tonic" businesses have, over a period of years, been exceedingly liberal in the use of guarantees in their advertising. Although no one has been successful in growing hair on a bald head, despite the frequency of guarantees to that effect, these businesses have not gone bankrupt. Two possibilities serve as an answer: the guarantee, regardless of its apparent ironclad nature, is full of loopholes, and the dissatisfied purchaser rather than risk ridicule does not attempt to get his money back.

SIMPLE DANDRUFF

Dandruff is actually a manifestation of a normal physiologic process. Dead keratinized cells are constantly being shed over the entire skin surface. On the scalp, the process is more noticeable and objectionable, because the hair enmeshes the flakes along with accumulated oily secretions and extraneous debris. The varying degrees of dandruff among people may be due to obvious physical factors or to constitutional predisposition. The continuous use of synthetic detergent shampoos, excessive use of irritating hair lotions or "tonics," overeating of sugars and starches, improper hygiene and poor general health have been defined by some authorities as aggravating the shedding of dead cells.

Treatment of Simple Dandruff.—When the amount of dandruff is objectionable and without apparent specific cause, a few simple measures faithfully executed will be of considerable value in its control. Daily gentle massage of the scalp will detach loose dandruff flakes from the scalp and subsequent brushing, in addition, will remove the flakes from the hair shafts. Shampoos as often as every three or four days in soft water may be necessary. Synthetic detergents may be drying. Their use in the specific treatment of dandruff is discouraged. They have obvious advantages in hard water areas. Simple hygienic principles dictate that brushes, combs and hats should not be borrowed or lent.

If strict adherence to these measures does not produce satisfactory results, a dermatologist should be consulted. Remedies should be applied only under the supervision of a physician, since they may contain irritating or sensitizing substances.

SEBORRHEA OF THE SCALP

Seborrhea is a functional disturbance of the sebaceous glands characterized by the occurrence of an excessive discharge of sebum (oil) forming white or yellowish greasy scales on the body. This condition does not necessarily limit itself to the scalp, but may be found on the face, chest, back or entire body. The cause of this disease, which has been the subject of controversy throughout medical circles for years, remains unknown. These few facts will illustrate that seborrhea is a medical problem and like other skin diseases should be diagnosed and treated only by physicians.

The relationship, if any, between seborrhea and loss of hair continues to be a subject of controversy among dermatologists who have studied the problem for years. There is still no proof that seborrhea influences loss of hair, regardless of the fact that it is present on a majority of scalps which are losing hair. As evidence against the likelihood of its role as the cause of baldness is the fact that seborrhea invariably affects the entire scalp, and yet hair is always lost in the characteristic patterns of ordinary baldness. In addition, regardless of the extensive nature of the disease, hair is lost only from the scalp, never from the chest or other hairy areas. Women who have a severe persistent seborrhea do not lose their hair. Nevertheless, seborrhea has become a by-word in hair "tonic" and hair and scalp treatment advertising.

All treatment is temporary; the disease is chronic with periods of quiescence and exacerbation. Although frequent shampoos may control the condition in some instances, more drastic treatment with medication may be required for effective results. In any event, seborrhea is a skin disease and, as such, should be treated by a physician. The use of dandruff removers and similar preparations should be discouraged, for they often contain ingredients which are capable of causing severe skin reactions and may, in some instances, aggravate the existing symptoms.

CAUSES OF BALDNESS

The most common and disturbing form of hair loss is "premature baldness," medically referred to as premature idiopathic alopecia. Although the oldest prescription on record is for the loss of hair and earliest recorded history indicates the problems of this condition, little more is known today about the actual cause, control or cure than was known then.

Premature baldness occurs almost exclusively in men during their second and third decades without any known recognizable disease. The loss of hair occurs in a characteristic pattern; first, over each eye with concomitant or subsequent loss of hair at the vertex, with the encroachment increasing until the top of the head is without hair.

The tendency toward premature baldness is hereditary. Although the endocrine glands are known to be an influential factor in normal growth, their relationship, if any, to the loss of hair in young men remains a mystery.

Evidence of the possible influence of inheritance and endocrine factors is the fact that eunochoid and male castrates do not develop ordinary baldness. One investigator succeeded in inducing typical early baldness of the male type in such persons by administering androgenic (male) hormones. Further enlargement of the bald areas was prevented by the discontinuation of the treatment; however, this discontinuation did not promote regrowth of lost hair. In addition, the androgenic hormones were without effect on those men whose families did not have a history of baldness. In all probability, frequent washing of hair, tight hats, continual use of electric lights, hot showers, sedentary city life and similar popularized theories are without significance.

Among the changes associated with advancing years is a loss of hair referred to as "senile" alopecia. Thinning of the hair of both men and women accompanies aging; however, such thinning is more frequent in men. The problem of senile alopecia from the medical point of view is the same as that of premature alopecia, but the psychologic implications of the loss of hair in the young adult are more acute and serious.

TREATMENT OF IMPENDING BALDNESS

To create a demand for hair-raising products, the male population is bombarded with advertising which aims at making them "bald" conscious. Some, without reason, become panicky and seek medical aid or resort to hair "specialists" and hair "tonics." Unless obvious, the first consideration is whether or not the man is actually losing more than an average amount of hair. Some shedding of hair is a normal process and, following any manipulation of the hair such as shampooing, brushing or combing, a noticeable hair fall can be expected. In addition, the average adult hair line indents somewhat over the eyes, replacing the straight hairline of childhood. Although it is true that male baldness originates in this area, many men have this normal patterning without becoming bald.

If the general health of the man is satisfactory and the loss of hair is progressive and in characteristic patterns, the condition is probably, in young men, premature idiopathic baldness or, in older men, senile baldness, referred to previously as ordinary baldness. Medical science does not know any device, substance or method which will regenerate hair lost in these conditions. Neither widely advertised salves, ointments, "tonics," ultraviolet rays, massage nor mechanical devices are effective.

Since this condition is, to the best of our knowledge, a result of constitutional factors or a combination of local and constitutional factors, a thorough physical examination should precede the diagnosis. In a few instances, a mild glandular disorder may exist which can be corrected and hair health improved. In others, diets high in sugars and starches may require modification, although the relationship between diet and hair loss is essentially speculative. The medical history of the person may reveal a recent severe physical or emotional strain which may have been responsible for hair loss. However, in any event, the diagnosis and any treatment of the conditions responsible for the progressive loss of hair are medical matters and should be entrusted only to a competent physician.

The claims of any one that he has developed a remedy for the control or cure of baldness, or that he has inherited a formula for a remedy, or that he has accidentally discovered a remedy or method, should be viewed with the greatest skepticism.

Clinical Notes, Suggestions and New Instruments

RESUSCITATION AFTER FORTY MINUTES OF CARDIAC ARREST

ARTHUR S. W. TOUROFF, M.D.
and
MILTON H. ADELMAN, M.D.
New York

True cardiac resuscitation has been defined by Fauteux[1] as "full and durable restoration, in due time to avoid eventual death, of the essential functions of a heart which has lost its power to propel blood and which, in all appearances, is unable to recover spontaneously its effective value as a pump." The same author listed the criteria of true cardiac resuscitation as follows: First, the heart must have ceased functioning as a pump, and, secondly, cardiac function must have been fully and permanently restored and life preserved. With the foregoing criteria in mind, we believe that the case about to be reported may be considered one of true cardiac resuscitation. The case is remarkable in that complete recovery followed cardiac arrest of forty minutes' duration. So far as we have been able to ascertain, such a prolonged period of arrest has been exceeded only in a case reported recently by Beck and his co-workers.[2]

REPORT OF A CASE.

D. H., a white boy, 16 years of age, was admitted to The Mount Sinai Hospital on Jan. 10, 1948, complaining of cough, intermittent fever and hemoptysis of seven months' duration. Physical examination disclosed extensive atelectasis of the left lung, which was assumed to be due to some type of occluding endobronchial lesion.

On January 12 the patient was examined bronchoscopically by Dr. Joseph L. Goldman, who reported the presence of a pinkish irregular mass which extended downward, from a point just below the orifice of the upper lobe bronchus of the left lung, to fill the lumen of the left main bronchus. Microscopic examination of specimens removed during bronchoscopic examination revealed "fibrosarcoma with acute inflammation." Accordingly, it was decided to proceed with operation.

Operation was performed by one of us (A. S. W. T.) on January 16. At 7:45 a. m., the patient was given a basal dose of tribromoethanol solution (5 Gm.) by rectum, in order to keep him unaware of the fact that operation was to be performed. Atropine sulfate, 1/150 grain (0.43 mg.), was administered intravenously at 8 a. m.

Inhalation anesthesia, consisting of cyclopropane and ether, was begun by one of us (M. H. A.) at 8:10 a. m. At 8:25 a. m., an oral endotracheal tube was introduced. This was connected to a carbon dioxide absorption, circle-filter anesthetic apparatus. Operation was begun at 8:27 a. m., the blood pressure then being 150 systolic and 90 diastolic and the pulse rate 140. A cannula was inserted into one of the veins at the ankle and a slow intravenous drip of isotonic sodium chloride solution begun. The patient was in the supine position on the operating table.

The left hemithorax was entered through the fourth intercostal space, anteriorly. After opening the pleura, an area of induration was palpated near the hilus of the lung and a pneumonectomy decided on by the surgeon. Sixty milligrams of procaine hydrochloride was injected into the tubing of the intravenous drip. The pulmonary artery was dissected from the pedicle with some difficulty, doubly clamped, divided and ligated with silk. At that juncture (9:05 a. m.), the patient became slightly cyanotic. Simultaneously, there was a moderate diminution in tidal volume and moist gurgling was heard in the endotracheal tube, from which blood was noted to issue freely. In addition, the blood pressure and temporal pulse could not be elicited. The cyanosis persisted for thirty seconds and was followed by deathlike pallor; respirations ceased, and the pupils dilated widely.

The exposed heart was inspected through the unopened pericardium and was found to be beating feebly and slowly, at a rate of approximately 50 per minute. Within a fraction of a minute all ventricular action ceased, but a few weak slow contractions could be noted in the region of the left auricle. Suddenly, the left ventricle exhibited momentary diffuse uncoordinated fibrillary movements, and then all cardiac action ceased. The time interval of these observations was less than one minute.

Therapy and Sequence of Events.—1. Artificial Respiration: Artificial respiration was begun immediately, by means of intermittent manual compression of the breathing bag of the anesthetic apparatus, and was maintained at a rate of 20 to 24 per minute. One hundred per cent oxygen was employed. Repeated aspiration of the tracheobronchial tree was performed, with a catheter. Approximately fifteen minutes after the onset of bleeding, bronchoscopic examination was performed and small amounts of liquid and clotted blood were removed. For two minutes after cardiac pulsation had ceased, the patient was apneic; then occasional gasping respirations at irregular intervals were noted.

2. Cardiac Massage: As soon as the heart beat was noted to have ceased, the patient was placed in the 15 degree Trendelenburg position and manual massage of the heart begun through the intact pericardium. This was maintained at a rate of 40 to 50 per minute. In massaging the heart, the surgeon used a compressing and gliding motion which began at the apex of the heart and moved toward the great vessels. The purpose of this particular maneuver was to attempt to maintain circulation. An interesting and constant pattern of cardiac action now was noted and was repeated whenever the cardiac massage was stopped. The auricles would contract feebly three or four times while the ventricles would exhibit diffuse

[2] Beck, C. S.; Pritchard, W. H., and Feil, H. S.: Ventricular Fibrillation of Long Duration Abolished by Electric Shock, J. A. M. A. **135**: 985-986 (Dec. 13) 1947.

ineffective fibrillary movements for a few seconds. Then all cardiac action would cease. The pattern of cardiac action was repeated constantly throughout the period of resuscitation.

3. Fluid and Drug Therapy: At the onset of the resuscitative period, the rate of the intravenous drip was increased, so that 750 cc. of citrated blood was administered during the episode. At 9:10 a. m., a mixture of 80 mg. of procaine hydrochloride and 1 mg. of epinephrine was injected into the left ventricular cavity. No alteration in cardiac action was noted. At 9:25 a. m., a mixture of 60 mg. of procaine hydrochloride and 0.5 mg. of epinephrine was injected into the left ventricular cavity, again without any effect. At 9:30 a. m., 80 mg. of procaine hydrochloride was injected into the tubing of the intravenous drip.

At 9:45 a. m., it was decided to incise the pericardium, in order to apply a dilute solution of procaine hydrochloride directly to the epicardium and also perform more effective cardiac massage. Accordingly, the pericardium was grasped with a hemostat and strong traction exerted, in preparation for incising the pericardial sac. At that juncture, the heart gave a sudden tumultuous extremely forceful beat and regular sinus rhythm was restored. Respirations returned promptly, the rhythm and tidal volumes being normal. The patient's deathlike pallor disappeared, and the pupils contracted considerably. The systolic pressure was found to be 100 mm. of mercury; the temporal pulse could be detected readily, and the rate was found to be 130 per minute.

Photograph of the patient prior to discharge from the hospital (Jan. 30, 1948).

In view of the fact that the pulmonary artery already had been divided, there was no alternative but to proceed with operation as rapidly as possible. During the remainder of the procedure, the patient's color was good; his systolic blood pressure ranged between 90 and 100 mm. and the pulse rate between 120 and 140. Pneumonectomy was completed at 10:45 a. m., the patient leaving the operating room in satisfactory condition.

Postoperative Course.—When he was returned to his room the patient's pulse was regular and strong. Slight cyanosis, which was present, was relieved by 100 per cent oxygen administered through a BLB mask. The patient was totally unresponsive and remained so until 9 p. m. that evening. At that time, he began to move all extremities and opened his eyes; he was incontinent of urine and feces. At 11 p. m. he began to speak and ask for water. His color was good; respirations and pulse were normal. The blood pressure was 110 systolic and 70 diastolic.

First Preoperative Day: In the morning, the patient was found to be rather somnolent, but responsive when called by name. Cursory neurologic examination revealed a bilateral Babinski reflex to be present. By evening the patient responded actively to orders and questions; he complained of vertigo and thoracic pain. By this time he was taking fluids well and had complete control of the rectal and vesical sphincters. No respiratory or circulatory disturbances were noted.

Second Postoperative Day: The patient's general condition was good. There was considerable emotional irritability. He responded rationally to all questions, but his speech was thick and slurred.

Fourth Postoperative Day: The patient's physical condition was good. Results of a careful neurologic examination were entirely negative. His speech was a little clearer; but memory, for recent and past events, was impaired. He was still emotionally labile. Orientation as to time and place was fair. Simple mathematic computations were well performed.

Fifth Postoperative Day: An electrocardiogram revealed sinus rhythm with low voltage of the T wave in leads 1 and 4; this was considered abnormal. Electroencephalographic observations showed an almost continuous and diffuse, but not quite symmetric, delta activity with frequencies as low as 1.5 per second; there was no focus. This was interpreted as due to severe diffuse cerebral dysfunction, as occurring in a great number of clinical conditions, such as multiple abscesses and encephalitis.

From the fifth postoperative day onward, the patient showed rapid improvement. By the eighth postoperative day he was out of bed. His speech, emotional stability and cerebration were decidedly improved. The electrocardiogram on that day was unchanged. By the twelfth postoperative day (January 28) the patient's recovery appeared to be complete and an electroencephalogram showed a large amount of diffuse and almost symmetrical activity (4 to 6 per second), appearing without focal accentuation. This was assumed to be due to a moderate degree of diffuse cerebral dysfunction without evidence of focal pathologic change in the cerebral hemispheres. The record was considered closer to normal than the previous one.

The patient was discharged on the fourteenth postoperative day (January 30), with the wound healed and in very good general physical condition (figure). Approximately two weeks after discharge, the patient was readmitted for a short period of observation. His emotional and mental reactions were normal; he was gaining weight and feeling well. An electrocardiogram, taken during this admission, revealed no definite abnormality. The patient was seen again, approximately four weeks later. At that time he had gained 33 pounds (15 Kg.) in weight and his condition was excellent. The electrocardiogram still was normal. The electroencephalogram revealed a small amount of diffuse and symmetric activity (6 per second) without focal accentuation. This was much less abnormal than the previous tracing. This type of record was considered indicative of a mild degree of diffuse cerebral dysfunction, as occurring in numerous conditions, (e. g., toxic states, encephalitis).

On March 10 the patient was again given a bronchoscopic examination by Dr. J. L. Goldman; a projection of tissue was observed on the posterolateral wall of the stump of the left main bronchus, approximately 3 cm. from the carina. A biopsy specimen was taken; the pathologist reported a mucosal fragment infiltrated by fibrosarcoma.

On March 22 a left exploratory thoracotomy and amputation of the stump of the left main bronchus were performed with nitrous oxide-oxygen-ether orotracheal anesthesia. The operation and anesthesia were uneventful; the patient left the hospital April 1.

The patient was seen again on November 4. His health was excellent; he was entirely free of symptoms. The electrocardiogram and electroencephalogram taken on that day were normal.

COMMENT

The occurrence of cardiac arrest in this case is best explained by a vagovagal reflex arising from active manipulation of the left pulmonary hilus and from irritation of the bronchial mucosa by intrabronchial hemorrhage. Adams and Hand[3] have emphasized factors of premedication, anesthesia and hypoxia in the production of increased vagal excitability; all these factors were present in our case.

It might be well to investigate the reason for this recovery which was remarkable not only because regular cardiac rhythm was restored forty minutes after cessation of the heart beat but also because the patient made a complete recovery. The primary therapeutic measures employed were cardiac massage, artificial respiration and the administration of procaine hydrochloride and epinephrine, both into the heart and intravenously. These, and some other measures available for cardiac resuscitation, will be reviewed briefly.

1. *Cardiac Massage.*—This is the prime factor in maintaining life until effective spontaneous cardiac action is restored. At the present time manual compression of the heart is the only means of maintaining some degree of circulation and cardiac output. Gunn[4] demonstrated experimentally that a dye injected into the right ventricle of an arrested heart appears in the lungs and carotid artery after a few cardiac compressions. Dripps and his co-workers[5] stated that proper cardiac massage can produce a systolic blood pressure of 60 to 70 mm. of mercury. Thus, it appears possible that cardiac massage often can maintain satisfactory cerebral circulation and that irreversible hypoxic damage to the brain can be prevented or reduced to a minimum. A moderate Trendelenburg position is advised to favor cerebral circulation.

The importance of early cardiac massage cannot be overemphasized, for only by such prompt treatment may one hope to combat the damaging effects of hypoxia on the central nervous system. Studies[6] indicate that the first three to five minutes of cerebral hypoxia, whatever the cause, are critical; after that interval irreversible cortical and medullary changes appear. Bailey,[7] on the basis of extensive experience in cardiac resuscitation, stated the opinion that it is hazardous to wait five minutes before instituting cardiac massage; he advocated initiation of cardiac massage within the third minute of the cardiac arrest when an abdominal incision is necessary to reach the heart. Nicholson[8] was even more uncompromising in his attitude and stated that the immediate institution of cardiac massage is indicated.

We are in accord with the opinion expressed by Nicholson, for we believe that procrastination constitutes a serious error in the management of these emergencies. In our case, we were fortunate in having the heart under direct observation at all times, so that no moments were lost in initiating manual compression. The sequence of events thereafter indicates clearly the effectiveness of cardiac massage, and we attribute the successful resuscitation of our patient primarily to the latter.

2. *Artificial Respiration.*—This is a therapeutic measure, the importance of which is surpassed only by that of cardiac massage. The term artificial respiration implies rhythmic insufflation of the lungs, preferably through an endotracheal tube, at the rate of 24 per minute and at a pressure not exceeding 15 mm. of mercury. The function of artificial respiration in cardiac resuscitation is twofold: first, to oxygenate blood in the pulmonary vascular circuit and, second, to aid in the maintenance of circulation. The latter point has been studied by Thompson and his co-workers,[9] who, with the aid of radioactive sodium, demonstrated the effectiveness of artificial respiration in producing movements of the blood column. In another study, Thompson and Rockey[10] observed, ". . . resuscitators employing positive and negative pressures were more efficient in circulating the blood, than those employing only positive pressure and release, or negative pressure and release." Pollock,[11] in his experimental study of cardiac massage, gave support to the work of Thompson; he demonstrated with excellent kymographic tracings that, in the presence of cardiac standstill, rhythmic insufflation of the lungs produces a transmitted pulse and minor fluctuations in blood pressure.

3. *Drug Therapy.*—It is traditional that the aforementioned treatment of cardiac arrest be supplemented by the parenteral administration of a variety of drugs, such as epinephrine and related sympathomimetic amines, nikethamide and digitalis preparations. Such therapeutic measures not only are wasteful of precious moments but are of decidedly questionable value, if not positively harmful when used indiscriminately. The use of digitalis preparations has no place in cardiac resuscitation. The fact that the full therapeutic effect of such drugs becomes manifest only in two or three hours after intravenous administration should be sufficient to eliminate them from consideration in these emergencies.[12] The use of nikethamide, as suggested by some,[13] is open to serious question; certainly, the stimulating effect which it may exert on an already depressed respiratory center may prove harmful. As for the effect of nikethamide on the heart, there is considerable doubt as to its value. In fact, recent studies[14] suggest that it may be deleterious.

The traditional intracardiac injection of epinephrine is now subject to criticism, and a reevaluation of this measure is necessary in the light of experimental and clinical observations. Bailey,[7] in his series of 40 cases of cardiac resuscitation, observed that not once was intracardiac epinephrine of value. (In 1 case, the prick of the intracardiac needle per se appeared to initiate regular sinus rhythm.) It is generally agreed that the intracardiac injection of epinephrine, through the unopened chest, is hazardous, since one usually is ignorant of the precise nature of the cardiac arrhythmia, e. g., cardiac standstill or ventricular fibrillation. In the presence of ventricular fibrillation, epinephrine will potentiate the arrhythmia; in cardiac standstill, epinephrine may precipitate ventricular fibrillation.[1] In either case, the surgeon is ignorant of what actually is happening. When the chest is open and satisfactory observation of cardiac action can be made, the use of epinephrine is suggested to combat cardiac flaccidity and dilatation. Fauteux's[1] experience indicates that the cautious intra-auricular injection of a mixture of barium chloride (5 to 10 mg.) and epinephrine (1 to 2 mg.) is effective in restoring cardiac tone. Beck[15] advised the use of a mixture of calcium chloride and epinephrine to combat cardiac dilatation. Two injections of epinephrine into the ventricle were ineffective in our case.

Recently, considerable attention has been focused on the intravenous use of procaine hydrochloride in the prevention and treatment of cardiac arrhythmias during anesthesia and on the use of procaine hydrochloride as a protection against ventricular fibrillation.[16] A final decision concerning the value of

the intravenous use of procaine hydrochloride in these conditions is not yet possible, because of conflicting reports. However, it appears that intravenous use of procaine hydrochloride offers some protection against experimental ventricular fibrillation and cardiac arrhythmias occurring with anesthesia. It also seems that ventricular fibrillation can be more readily controlled by direct electric shock therapy when combined with intravenous use of procaine hydrochloride than when used alone.

In our case, 80 mg. of procaine hydrochloride was administered intravenously before the accident occurred; this was in keeping with our practice of giving an initial dose of 75 to 100 mg. of procaine hydrochloride intravenously when lobectomy or pneumonectomy is planned. The later doses of intracardiac procaine hydrochloride were given either alone or in combination with epinephrine. In both circumstances, procaine hydrochloride was used to prevent the onset of ventricular fibrillation by the mechanical irritation of cardiac massage and by the injected epinephrine. One cannot be dogmatic in evaluating the role of procaine hydrochloride in this successful resuscitation. It can be stated only that the drug had no untoward effect (cardiac dilatation and flaccidity) and that it may have prevented protracted ventricular fibrillation. It is significant that, in spite of the intracardiac administration of epinephrine and the use of continuous cardiac massage, only very transient periods of fibrillary movements were observed.

Unquestionably, a major factor in our successful resuscitation was the fact that the patient was young. The chances for restoration of action in cardiac standstill and for control of ventricular fibrillation are best in the absence of myocardial damage. This is most apt to occur in young subjects.

The sudden return of regular sinus rhythm in our case occurred with clamping and traction of the pericardium. It appears unlikely that this was a purely coincidental or fortuitous event, and it seems reasonable to believe that some potent stimulatory reflex was initiated to restore cardiac action. The nature and pathway of this reflex merely can be assumed. Coffey and his co-workers [17] have described a pathway from the pericardium, via the phrenic nerve, to the superior sympathetic cervical ganglion, and it is possible that a powerful stimulus, traversing this pathway, served to initiate the cardiac action.

4. *The Problem of Ventricular Fibrillation.*—Ventricular fibrillation, in contrast to cardiac arrest, presents a unique problem. In the former, it first is necessary to stop the fibrillary movements before one can hope to restore regular sinus rhythm. Cardiac massage per se will not stop fibrillation; on the contrary, it may potentiate the arrhythmia. With these points in mind, Beck and his co-workers [2] have used an electrical apparatus to shock and defibrillate the heart. The clinical effectiveness of the apparatus already has been confirmed. Procaine hydrochloride has been advised as an adjuvant in electrical defibrillation, and Mautz [16d] has shown that intravenous use of procaine hydrochloride, when combined with electrical shock, restored a coordinated beat in practically all of the experimental animals with ventricular fibrillation, whereas electrical shock alone was successful in only one half of the animals. In the absence of a defibrillating apparatus, intra-auricular injection of procaine hydrochloride and cardiac massage should be used, in the hope of controlling the fibrillation.

SUMMARY

A case of cardiac arrest of forty minutes' duration, occurring during pneumonectomy, with full and complete recovery is reported. The therapeutic measures used were immediate cardiac massage, artificial respiration, intracardiac use of epinephrine and intravenous use of procaine hydrochloride. Regular sinus rhythm appeared following strong traction on the pericardium. The therapy of cardiac standstill is discussed.

Council on Physical Medicine

REPORTS OF THE COUNCIL

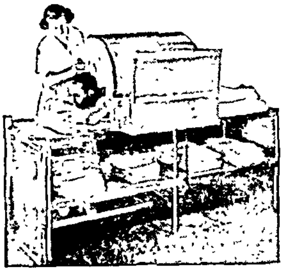
The Council on Physical Medicine has authorized publication of the following reports. Howard A. Carter, *Secretary.*

MOISTAIRE HEAT THERAPY UNIT MODEL 420 ACCEPTABLE

Manufacturer: The Ries Corporation, 515 South Aiken Avenue, Pittsburgh 6.

The Moistaire Heat Therapy Unit Model 420 is the same as the Saturated Air Fever Therapy Unit (Equipment Service Company, Pittsburgh) that was listed in Apparatus Accepted, Sept. 30, 1947. Certain improvements have been made, but in addition the apparatus has been renamed and the Ries Corporation has succeeded the Equipment Service Company.

This apparatus is essentially a stainless steel table bearing a cabinet of such shape and size that only the head and feet of the subject project from the chamber in which the warmed water-vapor is applied to the subject's body; the unit includes the table, the treatment hood and tank, the recirculating unit, moisture-proof curtains, a latex mattress with moisture-proof covering and a 3,800 cc. (4 quart) container for water. The table measures 76 cm. (30 inches) in height, 67 cm. (26½ inches) in width and 183 cm. (72 inches) in length. The mattress measures 61 by 173 by 6½ cm. (24 by 72 by 2½ inches). The unit as a whole weighs 180 Kg. (400 pounds); the shipping weight is 230 Kg. (505 pounds). The motor requires a 110 to 115 volt 60-cycle alternating current and draws 1,190 watts (12 amperes).



Moistaire Heat Therapy Unit Model 420.

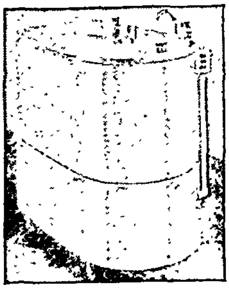
During a treatment, air saturated at a water temperature of about 54.4 C. (130 F.) enters the treatment hood. Here the temperature falls to about 50.5 C. (123 F.) before the air returns to the conditioning device. Thus saturation is assured.

The Council was furnished with evidence that this apparatus has given satisfactory service in the hands of practicing physicians and is well adapted to its purpose. The Council on Physical Medicine voted to include the Moistaire Heat Therapy Unit Model 420 in its list of accepted devices.

ROCKE HYDROTHERAPY BATHS MODELS 31 AND 41 ACCEPTABLE

Manufacturer: Wm. Rocke Co., Inc., 623 Madison St., Evanston, Ill.

The Rocke Hydrotherapy Baths are convenient devices for immersing part or all of the body in water. Both are provided with means for agitating the water. Model 31 is intended for the patient's arms or legs only; model 41 is large enough to immerse the patient, in the sitting position, up to the neck.



Rocke Hydrotherapy Bath Model 41.

Model 31 is made of anodized aluminum in one piece and has a capacity of 75 liters (20 gallons). It stands 86 cm. (34 inches) high and weighs 52 Kg. (115 pounds). When crated for domestic shipment it measures 73 by 67 by 95 cm. (28¾ by 26½ by 37⅓ inches) and weighs 63 Kg. (140 pounds). The foreign shipping weight is 68 Kg. (150 pounds). This model has two switches, one for the circulator power unit (¼ horsepower motor) and the other for the drain pump (a ⅒ horsepower motor). Motors can be supplied to run on either 110-120 or on 220-230 volts of alternating current, and the same for direct current; the power consumption is 400 watts.

Model 41 is made of stainless steel, seamlessly welded with a beaded rim, and holds 150 to 190 liters (40 to 50 gallons). The actual dimensions of the model 41 are 90 high by 56 wide by 107 cm. long (35 by 22 by 42 inches). When crated for domestic shipment it measures 116 by 75 by 100 cm. (45½ by 29½ by 39½ inches) and weighs 120 Kg. (265 pounds); the foreign shipping weight is 130 Kg. (290 pounds). This model has two ¼ horsepower motors for the circulator unit and a ⅒ horsepower motor for the drain pump. The types of current needed are the same as for model 31, but the power consumption is 800 watts.

The Council obtained evidence that these two devices are well constructed, safe and efficient. Model 31 is very much the same as the apparatus the acceptance of which was announced in THE JOURNAL of Nov. 13, 1943, page 701.

The Council on Physical Medicine voted to include the Rocke Hydrotherapy Baths, Models 31 and 41, in its list of accepted devices.

SILVER MICRONIC HEARING AID, MODELS 202 M AND 202 C ACCEPTABLE

Manufacturer: Micronic Company, 727 Atlantic Avenue, Boston 11.

These two instruments are substantially similar except that they are provided with magnetic and crystal types of receivers respectively. A single case contains amplifier, microphone and batteries.

Silver Micronic Hearing Aid, Models 202C & 202 M.

The outside dimensions of the case, including control switches but excluding clothing clips, are 107 by 55 by 20 mm. (4¼ by 2⅙ by ⅘ inch). Its weight, including batteries and crystal receiver, is 156 Gm. (5½ ounces).

Battery Data:

	Milliamperes
A Battery	50
B Battery magnetic receiver (quiet)	0.5
B Battery magnetic receiver in presence of sound	0.6
B Battery crystal receiver (quiet)	0.4
B Battery crystal receiver in presence of sound	0.5

The results of the performance tests of the Micronic are as follows:

Micronic Model 202 M Hearing Aid

				Articulation Scores	
Subject	Tone Setting	Volume	Acoustic Gain	Micronic 202 M	Reference
A	1	½	53 db.	81%	80%
B	3	⅞	47 db.	83%	77%

Micronic Model 202 C Hearing Aid

				Articulation Scores	
Subject	Tone Setting	Volume	Acoustic Gain	Micronic 202 C	Reference
A	1	½	53 db.	81%	80%
B	3	⅞	43 db.	80%	77%

Both subjects are habitual users of hearing aids. A's deafness is of the mixed type with 47 decibel loss for speech. Subject B has conductive deafness with 49 decibel loss for speech.

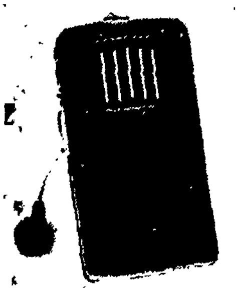
The Council on Physical Medicine voted to include the Silver Micronic Hearing Aid, Models 202 M and 202 C, in its list of accepted devices.

TONEMASTER MODEL ROYAL HEARING AID ACCEPTABLE

Manufacturer: Tonemasters, Inc., 1627 Pacific Avenue, Dallas 1, Texas.

The Tonemaster Model Royal Hearing Aid is a self-contained type hearing aid.

The dimensions of the instrument, including the clothing clips, are 119 by 65 by 23 mm. (4¾ by 2½ by 15/16 inch). The weight, including batteries, cord and magnetic receiver, is 238 Gm. (8.4 ounces).



Tonemaster Model Royal Hearing Aid.

Battery Data:

	Milliamperes
A Battery	41
B Battery (quiet)	0.58
B Battery in presence of sound	0.32

The results of the performance tests of the Tonemaster are as follows:

				Articulation Scores	
Subject	Tone Setting	Volume	Acoustic Gain	Tonemaster	Reference
A	Vertical	Full	51 db.	86%	80%
B	Middle	Full	52 db.	90%	77%

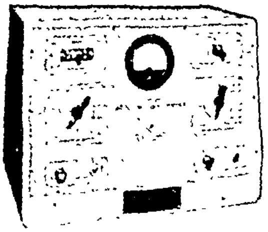
Both subjects are habitual users of hearing aids. A's deafness is of the mixed type with 47 decibel loss for speech. Subject B has conductive deafness with 49 decibel loss for speech.

The Council on Physical Medicine voted to include the Tonemaster Model Royal Hearing Aid in its list of accepted devices.

GOLSETH-FIZZELL CONSTANT CURRENT IMPULSE STIMULATOR, MODEL DS, ACCEPTABLE

Manufacturer: Chicago Medical Electronics Laboratory, Inc. 214 Ward Building, Battle Creek, Mich.

The Golseth-Fizzell Constant Current Impulse Stimulator, Model DS, with Electronic Timing Control, is an instrument designed to deliver direct-current stimuli in the diagnosis and treatment of nervous and muscular disorders. The apparatus is housed in a rectangular case that is provided with a handle and weighs about 13 Kg. (28 pounds). It measures 42 by 30 by 28 cm. (16½ by 12 by 11 inches) and operates on 115 volt 60 cycle alternating current. All the necessary accessories are carried within the cabinet cover.



Golseth-Fizzell Constant Current Impulse Stimulator, Model DS.

The duration of the impulse can be set at various predetermined values ranging from 1 up to 1,500 milliseconds. The interval between impulses can be set at 1, 5, 12, 1,000 or 4,000 milliseconds. The current intensity is registered from 0 to 25 milliamperes on a well damped milliammeter, and a potentiometer permits easy adjustment of the intensity. The dispersive electrodes furnished are round, flat metal disks 4.5 cm. and 3.25 cm. in diameter. The two active electrodes furnished are 1 and 2 cm. in diameter. The following diagnostic or prognostic tests can be made with the instrument: (1) galvanic tetanus ratio, (2) rheobase measurement, (3) chronaxis measurement, (4) strength-duration curve and (5) repetitive stimuli test.

Evidence was obtained from an acceptable clinic that the device was satisfactory for the aforementioned purposes. The Council on Physical Medicine voted to include the Golseth-Fizzell Constant Current Impulse Stimulator, Model DS, in its list of accepted devices.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

Austin Smith, M.D., *Secretary.*

LIPO-ADRENAL CORTEX.—An oil-soluble extract of hog adrenal glands concentrated by fractionation and containing crystalline biologically active constituents of what are considered to be 17-hydroxycorticosterone, 11 dehydro-17-hydroxycorticosterone and corticosterone and a noncrystallizable amount of 11-dehydrocorticosterone. The extract is practically free of epinephrine. It is assayed biologically according to the survival growth method of Cartland and Kuizenga (*Am. J. Physiol.* **117**:678, 1936) and the muscle-work test of Ingle (*Endocrinology* **34**:191, 1944).

Actions and Uses.—Lipo-Adrenal Cortex is employed for the same indications as for Adrenal Cortex Extract, but is supplied in oil solution only for intramuscular injection when more prolonged absorption is desired.

Dosage.—The dosage varies according to the degree of cortical insufficiency and should be governed by the clinical response. In crisis or the presence of infection or other complications as much as 2 to 3 cc. daily may be required, while 1 to 2 cc. daily may be sufficient for maintenance. Sodium salts are of definite value to supplement adrenal cortex therapy.

It should be borne in mind that lipo-adrenal cortex has approximately ten times the cortical activity of adrenal cortex extract and because it is administered in oil solution it should never be injected intravenously.

Preparation.—

Lipo-adrenal cortex is prepared by a method described by Kuizenga, Wick, Ingle, Nelson and Cartland (*J. Biol. Chem.* **147**:561, 1943). Frozen hog adrenal glands are extracted with chilled acetone and the gland residue removed by filtration. Sufficient water is then added to the acetone extract to make a 60 per cent acetone solution. A liquid fat fraction which separates is extracted with 20 per cent acetone, and the combined 60 per cent and 20 per cent acetone extracts are concentrated *in vacuo* to remove the acetone. The aqueous solution is then extracted with petroleum ether, followed by extraction with ethylene dichloride to obtain the active fraction. The ethylene dichloride solution is concentrated *in vacuo* below 40 C. and the residue dissolved in 95 per cent alcohol. Residual amounts of fat and cholesterol are removed by extraction of aqueous alcohol solutions with petroleum ether, which is done first from 70 per cent ethyl alcohol, then from 50 per cent methyl alcohol and, finally, from 30 per cent methyl alcohol. The 30 per cent methanol solution, free of petroleum ether-soluble material, is concentrated to remove alcohol and the cloudy aqueous solution is extracted with ethyl acetate. Acidic and basic substances are removed by washing the ethyl acetate solution with sodium carbonate, followed by 0.5 N HCl and, finally, distilled water. The ethyl acetate solution is dried with anhydrous $MgSO_4$. The dry concentrate from ethyl acetate is dissolved in acetone and the required amount of cotton seed oil and 0.5 per cent chlorobutanol is added. The acetone is completely removed *in vacuo* with a stream of N_2 gas and the resulting oil solution is sterilized by Seitz filtration.

The Upjohn Company, Kalamazoo, Mich.

Solution Lipo-Adrenal Cortex: 1 cc. and 5 cc. vials. Each cubic centimeter contains not more than 7.5 mg. of gland extractive solids having a potency of 40 rat units (Survival-Growth) and the equivalent in biological activity to 2 mg. of 11-dehydro-17-hydroxycorticosterone (Muscle-Work Test) in cottonseed oil. Preserved with chlorobutanol 0.5 per cent.

PERTUSSIS VACCINE COMBINED WITH TETANUS TOXOID.—A combination of pertussis-tetanus antigens prepared by suspending 40,000 million phase I, *H. pertussis* organisms in each cubic centimeter of fluid tetanus toxoid of the potency required by the National Institute of Health.

Actions and Uses.—Pertussis vaccine combined with tetanus toxoid is employed for the simultaneous active immunization of persons susceptible to both these infections. The combination is suitable for initial basic immunization as well as for follow-up stimulation because the dosage intervals for satisfactory results are similar for both antigens. It is intended primarily for use when it is considered expedient or preferable to administer diphtheria immunization separately.

Dosage.—For basic immunization of infants, three subcutaneous injections consisting of 0.5 cc., 1.0 cc., and 1.0 cc. are administered consecutively at intervals of one month. For use as a "booster" to stimulate greater and more prolonged immunity, a single follow-up dose of 1.0 cc. is recommended one year after basic immunization has been completed.

Cutter Laboratories, Berkeley, Calif.

Tetanus Toxoid and Bacterial Vaccine Made from H. Pertussis Combined: 2.5 cc. (one complete immunization) and 10 cc. (four complete immunizations) vials. 40,000 million phase I, *H. pertussis* per cc. Preserved with sodium ethylmercuri thiosalicylate 1 : 10,000.

PERTUSSIS IMMUNE SERUM (HUMAN) (See New and Nonofficial Remedies 1948, p. 487).

The following dosage form has been accepted:

Cutter Laboratories, Berkeley, Calif.

Antipertussis Serum (Human): A highly purified and concentrated globulin prepared from human donors immunized with *H. pertussis* vaccine. Preserved with sodium ethylmercurithiosalicylate 1 : 10,000. Each vial contains 2.5 cc., which represents the initial dose. Dose may be repeated as often as indicated by the condition of the patient.

THIAMINE HYDROCHLORIDE-U. S. P. (See New and Nonofficial Remedies 1948, p. 548).

The following dosage form has been accepted:

Cole Chemical Company, St. Louis 8

Solution Thiamine Hydrochloride: 15 mg. and 30 mg. per 30 cc. bottles and 475 cc. and 3.78 liter bottles.

Tablets Thiamine Hydrochloride: 1 mg., 3 mg. and 5 mg.

ESTROGENIC SUBSTANCES (WATER INSOLUBLE) (See New and Nonofficial Remedies 1948, p. 370).

The following dosage form has been accepted:

Ayerst, McKenna & Harrison, Ltd., New York

Aqueous Suspension Estrogenic Substances: 10,000 I. U. and 20,000 I. U. per cc., 10 cc. vials; 50,000 I. U. per cc., 5 cc. vials.

DIENESTROL (See New and Nonofficial Remedies 1948, p. 377).

The following dosage form has been accepted:

Carroll Dunham Smith Pharmacal Co., New Brunswick, N. J.

Tablets Dienestrol: 0.1 mg. and 0.5 mg.

STREPTOMYCIN (See New and Nonofficial Remedies 1948, p. 159).

The following additional dosage form has been accepted:

The Wm. S. Merrell Co., Cincinnati 15

Streptomycin Calcium Chloride Complex: 6.5 Gm. vials equivalent in activity to 5 Gm. of streptomycin base.

SULFAMERAZINE-U. S. P. (See New and Nonofficial Remedies 1948, p. 134).

The following dosage form has been accepted:

American Pharmaceutical Company, New York 18

Tablets Sulfamerazine: 0.5 Gm.

SODIUM ASCORBATE INJECTION-U.S.P. (See New and Nonofficial Remedies 1948, p. 561).

The following dosage form has been accepted:

William H. Rorer, Inc., Philadelphia 6

Solution Sodium Ascorbate: 100 mg. per cc., 5 cc. and 10 cc. ampuls. Each cc. contains sodium ascorbate equivalent to 100 mg. of ascorbic acid, stabilized with thiourea .01 per cent in sterile aqueous solution.

TYROTHRICIN (See New and Nonofficial Remedies 1948, p. 66).

The following dosage form has been accepted:

S. B. Penick & Company, New York 7

Tyrothricin: Bulk. 100 Gm., 500 Gm. and 1,000 Gm. glass jars.

CONTRACEPTIVE JELLIES AND CREAMS (See New and Nonofficial Remedies 1948, p. 286).

The following dosage form has been accepted:

Julius Schmid, Inc., New York 19

Ramses Vaginal Jelly: 143 Gm. collapsible tubes.

SATURDAY, MARCH 26, 1949

DEXTRAN AS A PLASMA SUBSTITUTE

Dextran, though scarcely known in this country, has been extensively studied in Sweden and has already achieved a fairly wide use there in intravenous solution as a means of treating various types of surgical shock. In this country, especially since the war and with the development of blood banks, whole blood and plasma have been more and more widely used for such a purpose. Nevertheless, the field for a satisfactory plasma substitute is far from closed. Indeed, considerable promise was held forth recently for newer preparations of gelatin solutions in the therapy of surgical shock of certain types. Earlier attempts to use such substances as acacia and pectin, while at first apparently successful, were doomed a priori because they were really foreign substances which the body had no way of metabolizing; they accumulated in the tissues and, if the amount injected was large, serious anatomic changes followed. Even gelatin, though a true protein, may not be utilized as such by the body. Although final evidence is lacking, infusions of gelatin probably reach the tissues and behave just as much as a foreign body as surgical gut, which, also a protein, is not really metabolized, but rather attacked and removed by phagocytes. Moreover, gelatin is classed as a fibrous protein, being long and stringlike, thus lacking the globular shape of albumin and most other plasma proteins, a difference of perhaps some importance.

Dextran is unlike other plasma substitutes in that it is composed of molecules of glucose, a substance which is, of course, normally metabolized by the body and indeed is an excellent source of energy. Dextran was first discovered by the Germans as an annoying complication sometimes encountered in sugar refineries. In the process of extraction of sugar from beets, a mucoid material would occasionally form which interfered with the speed of filtration. This material was observed only in sugar solutions which happened to be infected with a bacterium later identified as Leuconostoc mesenteroides. This organism had the remarkable property of joining glucose molecules in long chains including side chains, thereby forming polysaccharides with molecular weights in the millions. Most of the recent work has been done in Sweden by biochemists working in close collaboration with the Swedish sugar beet industry.[1]

Dextran was first prepared and then hydrolyzed so that it attained a molecular weight of about 100,000, which is close to that of plasma albumin. Various solutions were then carefully prepared and injected intravenously as a plasma substitute. The basic work in animals was carried on by Grönwall and Ingelman,[2] who found that the solution was well tolerated and seemed rather effective in treating experimental shock. It was then injected in human beings at the Central Hospital in Örebro by Bohmansson, Rosenkvist, Thorsén and Wilander.[3] The earlier solutions were tested in hopeless cases of cancer. Difficulty was experienced in producing a solution of constant composition, but a more or less uniform preparation was finally obtained which has been widely used in thousands of cases and shown to be almost entirely free of untoward reactions and with definite physiologic and therapeutic properties.

As used in Sweden at the present time, a 6 per cent dextran solution in 0.9 per cent sodium chloride solution is injected intravenously in amounts of 400 cc. up to as much as 3,000 cc. in the treatment of shock due largely to loss of plasma such as in burns, peritonitis and postoperative and post-traumatic states, and also as a prophylactic injection when shock is feared. Its effect in elevating low blood pressure is prompt and lasting in the cases described. One of its uniform actions is a rise in the sedimentation rate, which reaches its maximum at the end of the infusion and then gradually returns to normal in the course of a few days. Chemical methods of measuring dextran have been devised, and these show that about 25 per cent of the material infused (presumably the smaller-sized particles) is excreted by the kidneys during the few hours immediately following, but that the level in the blood itself falls rather slowly over the course of about four days. Study of the tissues following infusion in animals shows no evidence that dextran has accumulated therein after leaving the blood stream. This suggests but does not prove that the polysaccharide is broken down to glucose and then metabolized. As might be expected hematocrit measurements show hemodilution following the infusion of dextran, although there seems to be a curious reversal of this effect for a few hours; i. e., the relative red cell volume falls rapidly at first, then returns to normal in about an hour, falling again during the sixth to eighth hour and remaining low for at least twenty-four hours thereafter. This is explained by the authors as due to the emptying of blood depots of red cells. Evidence of renal or hepatic damage has not been seen, although the authors frankly admit that this possibility cannot be eliminated until several years have passed.

[3] Bohmansson, G.; Rosenkvist, H.; Thorsén, G., and Wilander, O.: Acta. Chir. Scandinav. 94:149, 1946.

An important though still theoretic advantage of dextran as a clinically safe and effective plasma substitute lies in its chemical nature. Being composed exclusively of glucose molecules, it is presumably metabolized by the body as a source of energy. This requires hydrolysis of the dextran by appropriate blood or tissue enzymes. Although suggestive evidence has been obtained as described in the foregoing, more data are necessary. Final proof will doubtless be forthcoming and, if it is true that dextran is actually hydrolyzed to glucose by the body, this theoretic advantage will become a real one. Only in this way can its superiority over other plasma substitutes which act as foreign substances be definitely established. Moreover, glucose is always needed, especially by patients receiving fluids intravenously; even if dextran furnishes glucose slowly, it could thus claim an additional therapeutic effect entirely apart from its colloidal property. The disadvantage of dextran because it is a long, stringlike molecule still remains, but this may be of much less importance. The development of this new therapeutic agent represents an example of what can be achieved through close association between medicine and industry.

THE CANADIAN NATIONAL HEALTH PROGRAM

At the November meeting of the Royal College of Physicians and Surgeons of Canada, the Honorable Paul Martin, Minister of National Health, reported progress of the National Health Program.[1] The minister expressed many points of view of the Canadian Government toward the medical profession which contrast sharply with views and attitude expressed by officials in the United States. Chief among these expressions of attitude was the statement that action would not be taken by the present Canadian Government under any program for the improvement of health services in Canada which would "stifle or destroy the liberty of the individual doctor." In order to provide better health for the citizens of its country, the Canadian Government looks first to the medical profession for leadership. Regimentation of doctors and professional personnel generally was considered to be ruinous to any expectation for health progress. Minister Martin stated, "In any sensible health plan the doctor holds a responsible position. Will we not want to see that doctors should continue to be free to serve their patients—not that they should become mere servants of the state." Discussing the responsibilities of the Provinces and the Federal Government in the program, Mr. Martin said that while health is of obvious national concern, it still must be considered primarily a provincial responsibility. Except for such services as inspection of food and drugs, quarantine, and health care for marine and Indian groups, planning and administration must be centered in the Province. It was considered folly to attempt to administer a centralized program from the dominion capitol. The clear responsibility of the Federal Government is emphasized to be that of cooperation with professional authorities in the coordination of efforts. The centralization of administration in the hope of creating efficiency was stated to be an illusion, "such centralization would badly serve the Canadian citizens."

Major objectives of the Canadian National Health Program, which has now been in operation some five months are stated to be: 1. Comprehensive and searching surveys of the Canadian health scene to be made by each province and a formulation by each province of its plans for the future. For this purpose grants of federal funds are made to the provinces. 2. The strengthening and extension of provincial health services through widening the range of preventive medicine, encouragement of public health research, the training of professional health workers and increased services in the fields of venereal disease, tuberculosis, cancer and mental illness. 3. The stimulation of provision for increased hospital accommodations to be encouraged by annual grants to the provinces up to a total of 65 million dollars over a period of five years. Grants would be based on a government contribution of from 1,000 to 1,500 for each hospital bed on the condition that the provinces match these grants.

In each case, stress is laid on the autonomy of the provinces as opposed to federal centralization. In spite of the fact that the program has been under way for such a short time, the provinces have actively cooperated by enthusiastically undertaking comprehensive surveys of health conditions in each of the provinces. Reviewing health progress in Canada during the last twenty years, the minister indicated that the general death rate had dropped 17 per cent; infant mortality had decreased by 44 per cent and maternal mortality had decreased 42 per cent. These are indicative of the effectiveness of present methods. The Canadian program stresses the importance of preventive medicine and the need for including the general practitioner and family doctor in plans for improved preventive work. In his closing remarks to the Royal College, the minister stated, "It should be your concern as leaders in Canadian medicine above all else tc guard against any action, whether it be by private agency or by government, that would lower the standard of medical practice. All our health programs would fail if the intangibles of medical progress—the quality of medical training, the doctor's instinct for selfless service—should in any degree be allowed to deteriorate."

---

[1] Martin, P.: Canada's National Health Program, read at the annual meeting of the Royal College of Physicians and Surgeons of Canada, Ottawa, Nov. 27, 1948.

The Canadian program when under full swing will cost the Government approximately 30 million dollars yearly. This amount will be distributed to the provinces in accordance with the needs and plans of each. The outstanding principle of the over-all federal program, and of the individual projects to be sponsored and carried out by each province, is that the greatest emphasis be placed on research, training of personnel and mass attacks on environmental factors of disease.

The reluctance of the Canadian Government to do anything which will interfere with the treatment of individual patients by individual physicians marks the basic philosophy of the Canadian plan.

PROVISIONAL DEFINITION OF POLIOMYELITIS VIRUS

Confusion regarding restrictions that should be applied to the term poliomyelitis virus, as opposed to other allied terms such as encephalomyelitis or encephalitis virus, has recently been considered by the Committee on Nomenclature of the National Foundation for Infantile Paralysis. Recommendations submitted were that the term poliomyelitis virus be used only to designate strains of the agent originally described as the cause of poliomyelitis in man, regardless of the source from which it may be recovered in nature. The identifying characteristics of this virus are the production of typical experimental disease in the monkey, the characteristics and distribution of histologic lesions in the spinal cord and brain of primates, the host range of the virus and its immunologic properties.

The clinical signs of disease in monkeys include fever, tremor and spasticity of muscles, usually followed by paralysis within a day or two. Severe generalized tremors are considered almost without exception to be pathognomonic of poliomyelitis. Pathologic lesions in the monkey essentially duplicate those in human beings in type and distribution. Spinal cord lesions are concentrated in the gray matter and primarily in the anterior horn cells. These are accompanied by focal and diffuse infiltration of leukocytes in areas of nerve cell damage. The cerebral cortex is noted to be generally spared and the deep cerebellar nuclei are generally involved.

Virus which produces the characteristic experimental disease in monkeys but does not infect other mammals may be considered poliomyelitis virus. In addition, certain strains isolated from typical cases have the capacity of producing paralytic poliomyelitis in mice, hamsters and cotton rats, but not in guinea pigs or rabbits. These strains appear to be immunologically related to the Lansing-1938 strain.

The committee stated that certain strains of encephalomyelitis virus of mice or "mouse poliomyelitis" (e. g., TO, FA, GD VII) and other viruses that produce lesions in the anterior horns of spinal cords in experimental animals but that do not otherwise satisfy criteria set down for poliomyelitis virus, should not be called "poliomyelitis virus," "mouse poliomyelitis virus" or "poliomyelitis-like virus."

MENTAL HEALTH AND INTERNATIONAL TENSIONS

Members of the UNESCO Conference on World Tensions[1] and the International Congress on Mental Health[2] have recently reported deliberations of major significance to world peace. The conclusions are based chiefly on the psychiatric premise that human emotions ("human nature") can now be scientifically studied, understood and even changed both for the individual and the group. Wars are unnecessary and are not considered inevitable consequences of human nature. Some needs are vital to all men: these include freedom from disease, insecurity and fear. Men everywhere desire at the same time fellowship, respect of their fellowmen and a chance for personal growth and development.

Inequalities in the use of modern productive power and resources were considered partially responsible for economic inequalities, insecurities and frustrations which lead to group and national conflict. One group may be wrongly led to see another group as a menace through acceptance of false images and oversimplified solutions. Myths, traditions and symbols of national pride handed down from generation to generation, plus current social and nationalistic symbols, are believed to hinder free movement of thought across artificial political boundaries of an interdependent world. The report suggests that neither continued colonial exploitation nor oppression of minorities is compatible with world peace.

As general standards of mental health are not universally applicable, a universal recommendation for the provision of types and numbers of psychiatric hospitals and clinics per unit of population cannot be made now. The primary concern of workers in the field of mental health is the development of methods for the release of human potentialities individually and collectively for the common good.

This newly clarified concept of the modifiability of human nature through insight into otherwise unconscious obstructions suggests ways of removing obstacles to personal and social development. The primary factors leading to better mental health are the acquirement by the individual of self knowledge and group social insight. Effort in behalf of one's own group can become compatible with effort in behalf of humanity generally.

ANTIBACTERIAL THERAPY OF TUBERCULOSIS

Modern antibacterial therapy of tuberculosis using streptomycin or sulfone compounds has never been hailed as a definitive self-sufficient method of treatment. Nevertheless, some authors of articles directed to the public have at times been less critical in their appraisal. A troublesome disregard of the limitations and hazards of treating tuberculosis with such drugs as streptomycin has become apparent. Physicians are pressed by anxious patients or their friends to use streptomycin instead of other well established methods.

A recent report of the Clinical Subcommittee of the Committee on Medical Research and Therapy of the American Trudeau Society (Medical Section of the National Tuberculosis Association) offers specific recommendations:

> Streptomycin appears to be most effective in the treatment of recent, acute, fairly extensive, and progressing pulmonary tuberculous lesions. Its use is particularly recommended in the treatment of tuberculous pneumonia. Symptomatic relief and roentgenologic improvement are common in many types of pulmonary tuberculosis soon after initiating therapy with streptomycin. In general, the degree of benefit is in direct proportion to the extent of the acute or exudative component of the total disease being treated. As relapse is common, streptomycin is best used as an adjunct to other standard forms of treatment. The following types of disease are regarded as especially suitable for streptomycin therapy: (*a*) acute bronchopneumonic tuberculosis with severe symptoms; (*b*) acute bronchogenic spread, particularly when of such a nature that much needed collapse therapy is prevented; and (*c*) chronic disseminated finely nodular tuberculosis without large confluent areas of destructive disease.

Streptomycin has, after less than four years of clinical trial, demonstrated its capability of producing unprecedented therapeutic benefits to patients with some types of tuberculosis which were most refractory to all previous medical and surgical treatment.[1] However, clinicians experienced in the use of the drug have emphasized repeatedly that its greatest usefulness is in conjunction with rest in bed, collapse therapy and surgical treatment. The earliest clinical reports which appeared about three years ago and others which followed warned against overoptimism and emphasized the peculiar limitations of antibacterial therapy in the treatment of a disease such as chronic tuberculosis with a lifelong tendency to relapse.

The Trudeau Society Committee said further:

> As streptomycin can only be used for periods of two to four months in the therapy of this chronic disease and because of the emergence of resistant organisms, it is imperative that streptomycin be used for a period during the course of the disease when the greatest benefit can be expected. . . . The Committee looks with disfavor on the practice of utilizing streptomycin prior to institutional care or as an alternative to collapse therapy in the hope that such treatment might be avoided.

This indicates clearly the necessity of integrating other therapeutic procedures with the timely administration of streptomycin to carefully selected patients. Physicians who do not have access to other medical and surgical facilities for treating tuberculosis should hesitate to administer streptomycin, especially for the treatment of pulmonary tuberculosis.

The hazards of streptomycin toxicity have been reduced steadily during the past two years; first, as a result of regulating dosage, and, second, by chemical modification of streptomycin to dihydrostreptomycin. Although dihydrostreptomycin is but slightly different in chemical structure from the parent compound, it appears to be distinctly less toxic, while retaining the therapeutic potentialities of streptomycin. Dihydrostreptomycin is not devoid, however, of toxic potentialities and its use should be subjected to restrictions similar to those advocated for streptomycin.

The Mycobacterium tuberculosis is yielding to the ever increasing pressure of scientific achievement. Improved methods of detecting tuberculosis, such as mass roentgenography, and improved methods of offensive action, such as present day chemotherapy and surgical treatment, have been developed greatly in recent years. During the past four years greater progress has been made against this enemy on these fronts than during the preceding forty years.

Current Comment

STANDARDS FOR CHILDREN'S CONVALESCENT HOMES

The Sub-Committee of the Committee on Public Health of the New York Academy of Medicine,[1] following a study of conditions in convalescent homes, has reported a set of standards for grading and licensing. At present the requirements of licensing vary from state to state; none is up to standard in many of the phases considered in the report and official inspections of convalescent homes are usually limited to the physical plant. The committee believes the main purpose of children's convalescent homes to be provision of good institutional care in an environment conducive to the betterment of physical and mental health. The report considers both generalized and specialized homes in detail and also types of patients suitable for treatment in convalescent homes. Age limits considered acceptable range from 2 to 12 years. Administrators should give preference to patients recovering from acute illness and accept patients for long term care only when a favorable prognosis is indicated. The specific functions of personnel including physicians, nurses, social workers and other attendants, are presented. To reduce cost to the patients, volunteer aid is encouraged. Many such institutions do not make use of the excellent opportunity which they are given to inculcate habits of health in the children under their supervision. In view of the large number of such homes which spring up from time to time throughout the country without adequate personnel and medical supervision, the recommendations made by the committee deserve wide attention.

ORGANIZATION SECTION

Washington Letter

(From a Special Correspondent)

March 21, 1949.

April Expected to be a Lively Congressional Month

With indications pointing to transmittal to Congress late in March of President Truman's national health message, Capitol Hill is preparing for an April launching of public hearings on compulsory health insurance and certain other less controversial measures pertaining to medical care and hospitalization.

Although the Senate will be the scene of most activity, the first hearings on a bill involving the medical sciences have been scheduled by the House. March 30 and 31 and April 1 have been set aside by the health subcommittee of the House Interstate and Foreign Commerce Committee to hear witnesses for and against the National Science Foundation bill. One of its provisions is for establishment of a special division for coordination of medical research conducted in the United States. The bill has been favorably reported by the Senate Labor and Public Welfare Committee.

The same committee has appointed a special subcommittee to handle pending legislation on federal subsidization of local public health units and expansion of the Hill-Burton hospital construction act. Senator Lister Hill (Democrat, Alabama) is chairman and other members are Senators Paul H. Douglas and Garrett L. Withers, Democrats, and Robert A. Taft and H. Alexander Smith, Republicans. It is considered likely that public hearings on these two bills will be held independently of hearings on general health legislation. The latter will be in charge of the standing subcommittee on health, headed by Senator James E. Murray (Democrat, Montana). On its calendar, besides the Murray-Wagner-Dingell bill will be the prospective omnibus health bills to be sponsored by Senators Taft and Smith and by Senator Hill. It is regarded almost as a certainty that the Murray subcommittee will open hearings some time in April on the Hill, Taft-Smith and Murray-Wagner-Dingell bills, the last named of which is still in process of being revised.

Arguments Heard for Increased Health Appropriations

Representatives of the American Cancer Society and the Medical College of the State of South Carolina were among those scheduled to be heard March 24-25 by a Senate appropriations subcommittee, in support of increased funds next year for the U. S. Public Health Service. Senator Taft announced he would go before the committee to urge approval of $2,000,000 for construction of a National Dental Research Institute building at Bethesda, Md. Senators Claude Pepper (Democrat, Florida) and John C. Stennis (Democrat, Mississippi) also planned to appear in support of increased funds for assistance to the states. Expansion of the federal mental health program was to be argued by Dr. Olin B. Chamberlain, of the Medical College of the State of South Carolina.

Christian Scientists Request Medical Care Concession

The House Ways and Means Committee, which is conducting hearings on social security extension that will continue for the remainder of March, has been asked to amend the pending bill H. R. 2892 so as to make Christian Science healing certifiable for medical care benefits which the bill proposes to extend to all needy persons. James Watt, manager of the Washington office of the Christian Science Committee on Publication, who laid the argument before the Ways and Means Committee, pointed out that two states—California and Illinois—recognize the principle.

"Should Christian Scientists, who themselves have contributed to the cause of old age assistance via social security and special taxes, be supplied with medical treatment but denied Christian Science treatment?" Mr. Watt asked. Christian Science treatment is a branch of the healing art. Christian Scientists have proved that reliance on material methods of healing is incompatible with reliance on divine aid through prayer and that it is not only incorrect but truly impossible under divine law to rely on both. This means that if they accept medical treatment, they are violating the very fundamentals of their religion. Although their method of treating the sick runs contrary to the prevailing systems of today, it is an integral part of their religion and they feel, in accordance with religious freedom, it is a constitutional right.

The proposed amendment is that "medical assistance," for purposes of the proposed law, be defined as meaning "medical or other legal remedial services for needy individuals."

Hearings on public assistance features of the proposed amendments, which began on February 28, were scheduled to be concluded March 22, following which the committee will take up extension of the law's provisions to the self-employed (including physicians, lawyers and other professional persons), farm and domestic labor and employees of hospitals and other nonprofit institutions.

Military Hospital Changes

Secretary of Defense James Forrestal, in late February, ordered the early closing of three Army and Navy general hospitals, reduction in status of three others and conversion of forty-eight station type hospitals to outpatient treatment centers. The changes, designed primarily to alleviate a serious shortage of medical and dental officers, had been recommended by the Hawley Board and subsequently indorsed by the Medical Advisory (Cooper) Committee. Also ordered effectuated by Secretary Forrestal on recommendation of the two advisory groups was joint staffing of medical facilities used jointly or in common by the armed services.

"Further, that in all geographical areas," said the Forrestal statement, "joint utilization be made of civilian consultants now employed by the medical services, and that professional services of outstanding specialists in the respective regular medical corps of the armed forces be more freely used in common."

General hospitals ordered decommissioned as soon as practicable are McCornack (Pasadena, Calif.) and the 22nd (Guam), both Army, and Pearl Harbor (Hawaii), Navy. The three reduced to station hospital status, all Army, are the 183rd at Anchorage, Alaska; Fort Totten, New York, and Tilton, at Camp Dix, N. J. The forty-eighth Army, Navy and Air Force station type hospitals which will be lowered to dispensary status are situated in eighteen states and the District of Columbia.

Record Figures on Streptomycin Production Revealed

On Dec. 31, 1948, the nation's stockpile of streptomycin was 6,100,000 Gm., the highest figure ever recorded, according to the Department of Commerce. Production during 1948 totaled 37,000,000 Gm., of which only 30 per cent was consumed by the domestic civilian market. Predicated on a reduction in price, wider application by the medical profession and availability of a less toxic product, the Department of Commerce anticipates a record demand and production of streptomycin in 1949. For penicillin, the Department's monthly (February) report on chemicals and drugs shows a production figure of 76,620 billion Oxford units in the first ten months of 1948. The top month was October, with 8,621 billion Oxford units.

Composite Committee Launches Antibrucellosis Campaign

At a special meeting in Washington on March 15 of representatives of public health, medical, livestock producer and certain other types of organizations, a decision was reached to form a permanent committee to advise Congress on control and eventual eradication of brucellosis. The American Medical Association, American Public Health Association, American Veterinary Medical Association and U. S. Public Health Service are among the score of organizations that will be invited to appoint representatives on the committee. Its temporary chairman is William Knox, of Fort Atkinson, Wis.

NATIONAL GRANGE ACTION ON HEALTH

REPORT OF ITS COMMITTEE ADOPTED AT ANNUAL SESSION

The members of the Interim Committee on Health have reviewed the National Grange Health Program of the past several years and believe it contains the basic recommendations for improving rural health. Looking ahead to next year on the basis of present developments and findings we recommend: (1) Continuation of the Interim Committee on Health; (2) a meeting of the members of the Interim Committee early in the year, possibly in conjunction with the American Medical Association Rural Health Conference, to map out activities for the year; (3) expansion of efforts to establish cooperative hospitals and clinics and to broaden prepayment plans to include surgical care; (4) increased attention to the hosptial construction program in the states so that rural communities needing hospitals will be able to receive federal aid and know how to get it before the program ends; (5) more research, education, and clinics to improve the greatly neglected mental health and dental condition of people, including cooperation of the Granges with the work of mental health associations; (6) efforts at all levels of government to stop pollution of streams and harbors.

Resolutions 18 by Carstensen; 47 by Holmes; 53 by Doss, and 85 by Fichter are covered by the following resolutions as approved by the committee.

Resolved:

1. That we reaffirm the resolutions on health adopted by the National Grange during its Annual Session in 1947.
2. We have studied the recommendations of the National Health Assembly held in Washington, D. C., May 1-4, 1948 and endorse the following:
   - (*a*) The program under the Hospital Survey and Construction Act should be continued and extended under a policy of flexibility permitting adaptation as may be required to meet changing needs. The present authorization of $75,000,000 per year should be increased in view of the urgent needs for the establishment of additional hospital beds and clinics and health centers in many areas of the country.
   - (*b*) The program under Public Law 725 and the hospital program of the Veterans Administration should be closely integrated in the interest of good planning.
   - (*c*) Hospitals within service areas should be functionally or organically associated with one another so that the patient may benefit from the resources of all.
   - (*d*) Governmental agencies having assumed responsibility for hospital care for patients and nongovernmental agencies purchasing hospital care should pay the established rate for such care.
   - (*e*) Hospitals, health departments and all other health agencies should seek every method for coordinating their efforts and integrating their functions in the interests of greater efficiency and service to the patient.
   - (*f*) Diagnostic clinics, outpatient services and home medical care and allied programs should be developed more extensively in extending health services for all.
   - (*g*) Hospitals should intensify and extend their basic activities in research and education.
   - (*h*) Preventive medical and dental service, and public health education should be carried out more widely as regular functions of the modern hospital.

     So far as possible, the general hospital should provide facilities for the care of all types of illness, with increased attention to the diagnosis and treatment of the patient with long term illness.
   - (*j*) The pressing need for additional facilities for the care of the mentally ill and persons with chronic diseases in general hospitals makes it necessary that special emphasis be given to this problem in the original state hospital plans and any revision of these plans under Public Law 725. A careful study to develop recommended standards is needed in this area for the guidance of state organizations under this Act.
   - (*k*) To develop and adequately meet good standards of patient care, it is recommended that all hospitals, nursing homes and other facilities for the care of the sick should meet at least minimum standards through the mechanism of licensure.
   - (*l*) The control of local facilities should be by the people in that locality on a cooperative or community basis, where possible with an elected board of directors, representative of lay and professional groups.
   - (*m*) Lay and professional organizations and governmental agencies should join in conducting a health education program and in developing plans for adequate facilities and health services which will include well coordinated and highly integrated networks of mobile units, clinics, community hospitals, district hospitals, regional hospitals and great medical centers.
3. That each state agency operating under the Hospital Survey and Construction Act consider carefully the advisability of organizing a rural hospital subcommittee, having representation from the major general farm organizations within the state and from the state land grant college, to advise the state concerning matters of importance in rural areas.
4. That adequate medical service for the prevention of illness, the care and relief of sickness and the promotion of a high level of physical and mental health should be available to all without regard to race, color, creed, residence or economic status.
5. That the principle of contributory health insurance should be the basic method of financing medical care for the large majority of the American people, in order to remove the burden of unpredictable sickness costs, abolish the economic carrier to adequate medical services and avoid the indignities of a means test.
6. That health insurance should be accompanied by such use of tax funds as may be required to:
   - (*a*) Furnish services which are public responsibilities.
   - (*b*) Supplement health insurance as necessary to provide adequate services for the whole population.
7. That voluntary prepayment group health plans organized on a community or collective bargaining level, embodying group practice and providing comprehensive service offer to their members the best modern medical care and are the best available means at this time of bringing about improved distribution of medical care in rural areas and should therefore be encouraged by every means.
8. That the people have the right to establish voluntary insurance plans on a cooperative basis and legal restrictions upon such right, now existing in a number of states, should be removed.
9. That high standards of service, efficient administration and reasonable costs require:
   - (*a*) Coordination of the services of physicians, hospitals and other health agencies in all phases of prevention, diagnosis and treatment.
   - (*b*) Efficient cooperation between the providers and the consumers of such services under the general principle that the responsibility for general policies, finances and administration should rest preponderantly on the lay group; for professional standards and procedures, upon the professional group; for mutual consultation on all matters of joint interest, upon both groups.
10. That the farm organizations, through the Conference Committee on Rural Health Services or other appropriate channels, explore the advisability of calling on the research and other resources of the U. S. Department of Agriculture and the land grant colleges in cooperation with health agencies to map out plans and programs for the continuous recruitment, training, distribution and financial support of doctors and other health workers in rural areas.

Compulsory Health Insurance

Whereas, Voluntary health plans are making rapid progress and these plans are generally run efficiently and to the satisfaction of members; therefore be it

Resolved, That people with comprehensive voluntary health service be exempted from any plan for compulsory health insurance should such health program be established.

Edward F. Holter.
George Sehlmeyer.
John F. Johnston.
Mrs. Zola Keith.
Mrs. Esther Seffren.
Mrs. Mabel Carr.

Coming Medical Meetings

Alabama, Medical Association of the State of, Montgomery, April 19-21. Dr. Douglas L. Cannon, 519 Dexter Ave., Montgomery 4, Secretary.

American Association for Thoracic Surgery, New Orleans, March 29-31. Dr. Brian Blades, George Washington University Hospital, Washington, D. C., Secretary.

American Association of Anatomists, Philadelphia, April 13-15. Dr. Normand L. Hoerr, 2109 Adelbert Road, Cleveland 6, Secretary.

American Association of Genito-Urinary Surgeons, White Sulphur Springs, W. Va., Greenbrier Hotel, May 9-11. Dr. Norris J. Heckel, 122 S. Michigan Ave., Chicago 3, Secretary.

American Association of Industrial Physicians and Surgeons, Detroit, Book-Cadillac and Statler Hotels, April 5-9. Dr. Edward C. Holmblad, 28 E. Jackson Blvd., Chicago 4, Managing Director.

American Association of Pathologists and Bacteriologists, Boston, April 15-16. Dr. Howard T. Karsner, 2085 Adelbert Road, Cleveland, Secretary.

American Association on Mental Deficiency, New Orleans, Hotel Roosevelt, April 27-30. Dr. Neil A. Dayton, Box 51, Mansfield Depot, Conn., Secretary.

American Broncho-Esophagological Association, Chicago, Drake Hotel, April 18-19. Dr. Edwin N. Broyles, 1100 N. Charles St., Baltimore 1, Secretary.

American College of Allergists, Chicago, April 14-17. Dr. Fred W. Wittich, 423 LaSalle Medical Bldg., Minneapolis 2, Secretary.

American College of Physicians, New York, March 28-April 1. Dr. George Morris Piersol, 4200 Pine St., Philadelphia 4. Secretary General.

American Industrial Hygiene Association, Detroit, Book-Cadillac and Statler Hotels, April 5-7. Dr. Henry F. Smyth Jr., 4400 Fifth Ave., Pittsburgh 13, Executive Secretary.

American Laryngological Association, New York, May 16-17. Dr. Louis H. Clerf, 1530 Locust St., Philadelphia, Secretary

American Laryngological, Rhinological and Otological Society, Chicago, Drake Hotel, April 18-20. Dr. C. Stewart Nash, 277 Alexander St., Rochester 7, New York, Secretary.

American Orthopedic Association, Colorado Springs, May 18-21. Dr. C. Leslie Mitchell, Henry Ford Hospital, Detroit 2, Secretary.

American Orthopsychiatric Association, Chicago, Stevens Hotel, April 4-6 Nina Ridenour, Ph.D., 25 W. 54th St., New York 19, Secretary.

American Otological Society, New York, May 18-19. Dr .Gordon D. Hoople, 713 E. Genesee St., Syracuse, N. Y., Secretary.

American Pediatric Society, Atlantic City, May 5-6. Dr. Henry G. Poncher, 1819 W. Polk St., Chicago 12, Secretary.

American Physiological Society, Detroit, April 19-22. Dr. Milton O. Lee, 2101 Constitution Ave., Washington 25, D. C., Executive Secretary.

American Society for Clinical Investigation, Atlantic City, May 2. Dr. Paul B. Beeson, Grady Hospital, Atlanta 3, Georgia, Secretary.

American Society for Experimental Pathology, Detroit, April 18-22. Dr. Frieda S. Robscheit-Robbins, 260 Crittenden Blvd., Rochester, N. Y., Secretary.

American Society for Pharmacology and Experimental Therapeutics, Detroit, April 18-22. Dr. Harvey B. Haag, Medical College of Virginia, Richmond 19, Secretary.

American Society for Research in Psychomatic Problems, Atlantic City, Chalfonte-Haddon Hall, April 30-May 1. Dr. Sydney G. Margolis, 714 Madison Ave., New York 24, Executive Secretary.

American Society of Biological Chemists, Detroit, April 17-22. Dr. Otto A. Bessey, 1853 W. Polk St., Chicago 12, Secretary.

American Surgical Association, St. Louis, April 20-22. Dr. Nathan Womack, University of Iowa, Iowa City, Secretary.

American Urological Association, Los Angeles, Hotel Biltmore, May 16-19. Dr. Thomas D. Moore, 899 Madison Ave., Memphis 3, Tenn., Secretary.

Arizona State Medical Association, Tucson, May 8-10. Dr. Frank J. Milloy, 15 E. Monroe St., Phoenix, Secretary.

Arkansas Medical Society, Little Rock, April 14-16. Dr. William R. Brooksher, 602 Garrison Ave., Fort Smith, Secretary.

Association of American Physicians, Atlantic City, May 3-4. Dr. Henry M. Thomas Jr., 1201 N. Calvert St., Baltimore 2, Secretary.

California Medical Association, Los Angeles, May 8-11. Dr. L. Henry Garland, 450 Sutter St., San Francisco 8, Secretary.

Connecticut State Medical Society, New Britain, State Teachers' College, May 3-5. Dr. Creighton Barker, 258 Church St., New Haven, Secretary.

Federation of American Societies for Experimental Biology, Detroit, April 18-22. Dr. Milton O. Lee, 2101 Constitution Ave., Washington 25, D. C., Secretary.

Florida Medical Association, Belleair, April 10-13. Dr. Robert B. McIver, 111 W[illegible] Secretary.

Georgia, [illegible] vannah, Hotel De Soto, May 10-13. Dr. Ed[illegible] ee St., N.E., Atlanta, Secretary.

Hawaii Territorial Medical Association, Honolulu, May 5-8. Dr. Harry L. Arnold Jr., 510 S. Beretania St., Honolulu, Secretary.

Illinois State Medical Society, Chicago, Palmer House, May 16-18. Dr. Harold M. Camp, 224 S. Main St., Monmouth, Secretary.

Iowa State Medical Society, Des Moines, April 18-21. Dr. Allan B. Phillips, 406 Sixth Ave., Des Moines 9, Secretary.

Kansas Medical Society, Topeka, May 9-12. Dr. D. D. Vermillion, 512 New England Bldg., Topeka, Secretary.

Louisiana State Medical Society, New Orleans, May 5-7. Dr. P. T. Talbot, 1430 Tulane Avenue, New Orleans 13, Secretary.

Maryland, Medical and Chirurgical Faculty of the State of, Baltimore, April 26-27. Dr. George H. Yeager, 1211 Cathedral St., Baltimore 1, Secretary.

Medical Library Association, Galveston, Texas, April 10-14. Miss Mildred R. Crowe, Medical College of Alabama Library, Birmingham 5, Ala., Secretary.

Minnesota State Medical Association, St. Paul, Municipal Auditorium, May 9-11. Dr. B. B. Souster, 496 Lowry Medical Arts Bldg., St. Paul 2, Secretary.

Mississippi State Medical Association, Biloxi, May 10-12. Dr. T. M. Dye, Box 295, Clarksdale, Secretary.

Missouri State Medical Association, Kansas City, March 27-30. Mr. T. R. O'Brien, 634 N. Grand Blvd., St. Louis 3, Secretary.

National Tuberculosis Association, Detroit, May 2-6. Dr. H. Stuart Willis, 1790 Broadway, New York 19, Secretary.

Nebraska State Medical Association, Omaha, Hotel Paxton, May 2-5. Dr. R. B. Adams, 416 Federal Securities Building, Lincoln 8, Nebraska, Secretary.

New Jersey, Medical Society of, Atlantic City, Hotel Ambassador, April 25-28. Dr. Earl L. Wood, 315 W. State St., Trenton 8, Secretary.

New Mexico Medical Society, Roswell, May 5-7. Dr. H. L. January, 221 W. Central Ave., Albuquerque, Secretary.

New York, Medical Society of the State of, Buffalo, Hotel Statler, May 2-6. Dr. Walter P. Anderton, 292 Madison Ave., New York 17, Secretary.

North Carolina, Medical Society of the State of, Pinehurst, The Carolina, May 9-11. Dr. Roscoe D. McMillan, P. O. Box 232, Red Springs, Secretary.

Ohio State Medical Association, Columbus, April 19-21. Mr. Charles S. Nelson, 79 E. State St., Columbus 15, Executive Secretary.

Oklahoma State Medical Association, Tulsa, Mayo Hotel, May 15-19. Mr. R. H. Graham, 210 Plaza Court Bldg., Oklahoma City, Secretary.

Rhode Island Medical Society, Providence, May 11-12. Dr. Morgan Cutts, 106 Francis St., Providence 3, Secretary.

Society of American Bacteriologists, Cincinnati, May 15-20. Dr. John Blair, Hospital For Joint Diseases, New York, Secretary.

Southern Branch, American Public Health Association, Dallas, Texas, Baker Hotel, April 14-16. Dr. George A. Denison, 600 S. Twentieth St., Birmingham, Ala., Secretary.

Southwest Allergy Forum, El Paso, Texas, Hotel Paso del Norte, April 4-5. Dr. O. E. Egbert, First National Bank Bldg., El Paso, Secretary.

Tennessee State Medical Association, Chattanooga, April 12-14. Dr. W. M. Hardy, 706 Church Street, Nashville 3, Secretary.

Texas, State Medical Association of, San Antonio, May 2-5. Dr. Harold Williams, 700 Guadalupe St., Austin, Secretary.

Western Association of Industrial Physicians and Surgeons, Los Angeles, Hotel Biltmore, May 7. Dr. Christopher Leggo, Crockett, Calif., Secretary.

Medical Legislation

STATE LEGISLATION

Arizona

Bills Introduced.—H. 181, to amend the law relating to public institutions, proposes that in any state or county institution supported wholly or in part by public funds in which hospital service is rendered or health treatments administered, licensed chiropractors shall be accorded equal rights and privileges with licensed practitioners of medicine and surgery and that the treatment of any patient therein who may so elect shall include without distinction, favor or discrimination the treatments, manipulations, adjustments and other services of a licensed chiropractor. Discrimination of the type prohibited by this proposal would constitute cause for the summary removal of any public officer or employee permitting or participating in such discrimination. H. 279 proposes the creation of a lien in favor of a hospital against any cause of action which an injured person might have, to the extent of hospital care and treatment furnished to such injured person. S. 100 proposes the enactment of a new osteopathic practice act. Licentiates under this act would be permitted, among other things, to perform the same duties and obligations and authorized to exercise all the same rights and privileges possessed by physicians and surgeons of other complete schools of medicine in the practice of their profession, except that no osteopathic physician or surgeon shall perform major surgery unless he has had two years of surgical training in a hospital approved for such training by the board or shall demonstrate to the board equivalent training, and the board shall certify in writing to the applicant his right to perform major surgery before engaging in any such duties.

Arkansas

Bill Enacted.—H. 23 has become act No. 131 of the Acts of 1919. It creates a financing board for Arkansas medical students and makes provisions for loans to medical students conditioned upon the recipient's residing in and practicing his profession in a community in Arkansas with a population of 2,000 or less for a period of five years following the completion of his internship.

California

Bills Introduced.—A. 2212 proposes a number of amendments to the **chiropractic practice act** among which is the following definition: "The practice of chiropractic shall consist of any or all acts essential to the application of chiropractic principles. Said acts are directed chiefly to the proposition of adjusting vertebral subluxations for the purpose of reducing obstructive pressure upon nerves where they lie in intervertebral foramina, or for reducing pressure upon the spinal cord." Chiropractic adjustment is defined as the voluntary and specific reestablishment of proper vertebral relationship for the purpose of correcting obstructive pressure upon spinal nerves or the spinal cord, and chiropractic utilities would be construed to mean any device, system, method or manner of procedure intended to facilitate the application of chiropractic principles in determining the presence or absence and correction of obstructive pressure on nervous tissue and/or the environmental stresses which initiate the adaptive changes causing such obstructive pressure, or the disclosure of any fact or facts consistent with the theory of chiropractic as defined in other provisions of the proposal. A. 2337, to amend the business and professions code, proposes the creation of a California **state board of psychologist examiners.** Certificates issued by this board would entitle a person to counsel, analyze and treat by methods usually employed by psychologists those patients who suffer from nervous and psychological conditions not definitely diagnosed as pathologic. A. 2789, to amend the labor code, proposes that the term physician shall include **drugless practitioners.**

Missouri

Bills Introduced.—H. 113, to amend the medical practice act, proposes to authorize the revocation of a license upon proof that a licentiate has accepted **in addition to his fee any rebate,** commission or any other type of payment, either directly or indirectly, in connection with the writing or filling of a prescription, except in those cases in which a licentiate compounds or dispenses his own prescriptions. H. 121 proposes to direct the curators of the University of Missouri to establish and conduct a **medical and surgical school** with a full and complete course of medical and surgical instruction.

New Jersey

Bill Introduced.—A. 317 proposes the creation of a **board of chiropractic examiners** and defines chiropractic as the theory and practice of nerve impulse control by vertebral adjustment by hand only for the purpose of removing a cause of disease. A licensee under this proposal would have the right in the examination of patients to use the neurocalometer, x-ray and other instruments necessary solely for the purpose of diagnosis or analysis.

New York

Bills Introduced.—A. 1871, to amend the public health law, proposes that every physician shall give notice to the health officer of the county, city, town or village wherein such person resides of every case of **cerebral palsy** under his care and of all new cases of cerebral palsy of which he learns. A. 2128 and S. 1929, to amend the education law, proposes the creation of a state **board of chiropractic examiners** and defines chiropractic as the science of locating and the removing of nerve interference in the human body, according to chiropractic principles, where such interference is the result of or caused by misalignment or subluxations of the vertebral column. A. 2233, to amend the education law, proposes regulations for the examining and licensing of persons desiring to practice **naturopathy** and proposes that a license to practice naturopathy shall not permit the holder thereof to administer internal toxic drugs or to perform major surgery. A. 2891 proposes to prohibit the sale of "**lithium sodium**" except on prescription by a person legally authorized to issue such prescription. A. 3030, to amend the education law, proposes to include within the definition of the practice of medicine the administration of anesthesia or **the practice of anesthesiology.** S. 1836, to amend the education law relating to the **definition of the practice of medicine**, proposes to include within such definition diagnosing, treating, operating or prescribing for mental or nervous disorders. S. 2023, to amend the education law, proposes to define the practice of medicine so as to include the **practice of naturopathy.** The proposal would also add a naturopath to the state board of medical examiners. Applicants for a license to practice naturopathy would be required to submit to an examination by the state board of medical examiners except that they would not be examined in major surgery and their license would not permit them to administer internal toxic drugs or to perform major surgery. S. 2045 proposes to create a lien in favor of every duly licensed physician to the extent of **emergency medical or surgical aid** or treatment rendered to persons injured as the result of negligence of any other person. S. 2196 proposes regulations for the licensing of unincorporated hospitals and **lying-in asylums.** S. 2402 proposes to authorize **hospitals supported in whole or in part by public funds** or by the solicitation of private subscriptions to which patients are admitted upon payment of a charge or fee or at which persons receive medical and/or surgical treatment upon payment of a charge or fee to employ physicians and/or surgeons under a contract or salary arrangement for the medical diagnosis and/or treatment of patients only when such diagnosis and/or treatment is a public charge. In all other cases such medical diagnosis and/or treatment shall be rendered to patients in such hospital independently of other hospital charges and under contractual relationship between the patient and the physician.

North Dakota

Bill Enacted.—S. 148 was approved Feb. 26, 1949. It amends the traffic law relating to persons operating motor vehicles while under the influence of **intoxicating liquor** by setting forth classifications of percentages established as the result of chemical tests of the defendant's blood and permits the results of such chemical tests to be admitted in evidence. No defendant, however, shall be required to submit to any chemical test without his consent.

Oklahoma

Bill Introduced.—S. 188 proposes the creation of a **lien in favor of hospitals** against cause of actions accruing to patients, to the extent of the hospital care furnished to such person. The lien created by this proposal would extend also to physicians for medical services rendered.

Oregon

Bill Introduced.—S. 338 proposes that no person shall furnish any **dangerous drug** except upon the prescription of a physician, dentist or veterinarian. "Dangerous drug" is defined to include hypnotic drug (acetylurea derivatives, barbituric acid or malonylurea derivatives, chloral, paraldehyde, phenylhydantoin derivatives), aminopyrine, amphetamine, cinchophen, diethyl-stilbestrol, ergot, oils of croton, rue, savin or tansy, sulfanilamide, extracts of glandular preparations, phenol and penicillin.

Pennsylvania

Bills Introduced.—H. 412 proposes amendments to the workmen's compensation act which would result in the enactment of an **occupational disease act.** H. 450 and H. 451 propose that medical service plan corporations shall include the services of **doctors of osteopathy.** H. 466 proposes the enactment of a **permissive sterilization act.** H. 502 proposes the **creation of a state laboratory** for the purpose of rendering assistance to the different coroners throughout the commonwealth in their investigation of all cases where death is sudden or violent and is of a suspicious nature and character to ascertain whether death was due to other than natural causes and in rendering assistance in all cases where autopsies are necessary and for the purpose of rendering toxicologic examinations of foodstuffs for the department of health in connection with outbreaks of gastroenteritis due to the ingestion of contaminated food. The chief of such laboratory would be required to be a legally qualified doctor of medicine duly trained to do pathologic work. H. 529, to amend the law relating to the treatment of **mental diseases and epileptics** in state hospitals, proposes that the word "qualified physician" shall mean a person licensed to practice osteopathy. H. 626 proposes to require every physician who treats or examines any blind person or persons with **impaired vision** approximating blindness to make a written report thereof to the department of welfare. H. 808 proposes the creation of a **lien in favor of hospitals** against causes of action possessed by patients therein, to the extent of services furnished to such patient by the hospital. S. 278 proposes to authorize the department of health to license institutions desiring to obtain from any pound in the jurisdiction **live dogs and cats** for the purpose of carrying on scientific and educational research activities. S. 279 would require all persons desiring to **practice osteopathy** in the state to undergo the same examination as that taken by physicians and surgeons and would repeal the existing osteopathic act except so far as it applied to persons already licensed thereunder. S. 280 proposes to increase the size of the state board of medical education and licensure by the **addition of an osteopathic member** and proposes that the powers and duties of the state board of osteopathic examiners and the osteopathic surgeons' examining board shall be taken over by the state board of medical education and licensure. S. 345 proposes to make it a misdemeanor for any person to experiment or operate in any manner whatsoever upon any **living dog or cat** for any purpose other than healing or curing such dog or cat. S. 385 proposes the creation of a **lien in favor of hospitals** on the proceeds of insurance policies for services rendered to persons injured in accidents entitled to payments from such proceeds.

Vermont

Bill Introduced.—H. 183 proposes that the medical practice act shall not prevent a duly licensed physician or surgeon of an adjoining state or of the Dominion of Canada from **coming into a town bordering thereon in this state** for the purpose of treating a sick or disabled person therein.

Washington

Bills Introduced.—H. 224 proposes the creation of a **medical disciplinary board** to hear and determine charges of unprofessional conduct against persons licensed to practice medicine and surgery. H. 252 proposes regulations for the licensing of hospitals and related institutions, and the appointment of a **state hospital council.** The proposal is broad enough to cover private as well as state and government operated institutions within the state. H. 258 proposes that any physician or surgeon performing an operation **shall make a written diagnosis** of the patient's condition and set forth therein the purpose of said operation stating what organs, glands or tissues are to be removed. A copy of this diagnosis shall be given to the patient or to his or her relative or designated agent and a copy shall be mailed or delivered to the health department. All excised parts, glands or tissue must be kept in a carefully labeled receptacle and properly preserved for a period of ten days after removal and must be delivered on written demand from the patient, relative or agent to whomsoever they designate. The proposal further makes it a misdemeanor for any physician or surgeon to perform an unnecessary operation, which is defined to mean a surgical operation performed in which no pathology was found to exist in parts removed or a surgical operation performed in pursuance to a wrong diagnosis or a surgical operation from which the patient could not reasonably be expected to receive the relief desired and as diagnosed. H. 261 proposes that the University of Washington School of Medicine be required to teach **courses in naturopathy, osteopathy and surgery, chiropractic, sanipractic, physio-medicine and surgery** and any other branch of the healing arts that is incorporated or the members of which are licensed to practice their respective professions in the state of Washington. H. 283 proposes to authorize the director of licenses to appoint a committee of examiners for **the practice of massotherapy,** which is defined as the method, art or science of treating the human body for hygienic or remedial purposes to maintain health and to establish a normal condition of the body and shall include all massage manipulations, passive and active remedial gymnastics and relaxing movements and manipulations with the hands or with any other agency or instrumentality designed to accomplish massage manipulations or gymnastics, or by mechanical gymnastics to promote physiologic action to bring about a normal condition of health and restore bodily functions to a normal condition. Licentiates would be permitted also to use electrotherapy, hydrotherapy and physical therapy as defined by the proposal. H. 304 proposes to require every hospital on demand to **render first aid** to any person requiring emergency assistance and would make the hospital and any physician or agent of the hospital liable for damages caused by the refusal so to do. H. 329 proposes to make it an act of **unprofessional conduct** for any person licensed to practice medicine and surgery, drugless treatment in any form or dentistry to accept any rebate, refund, commission or unearned discount, whether in the form of money or otherwise, as compensation for referring patients to any person, firm, corporation or association. H. 363, to **amend the medical practice act,** proposes that applicants must have graduated from a medical school having standards no less than the standards of the Medical School of the University of Washington. H. 399 proposes the establishment of **cancer clinics** at various places throughout the state and authorizes the state director of health to appoint physicians to serve at such clinics on such terms and compensation as the state director of health shall determine. H. 493 proposes the enactment of a hospital survey and construction act for the purpose of making an **inventory of existing hospitals,** a survey of additional needed facilities and the development and administration of a construction program for such needed facilities. The Director of the State Department of Health is designated as the agent to apply for and receive federal funds to assist the state in its project and is also directed to appoint an Advisory Hospital Council to advise and consult with the department of health in carrying out the administration of the act. H. 550 proposes to permit the board of medical examiners to accept the certificates of the **National Board of Medical Examiners** from applicants for licensure to practice medicine in the state. S. 233 proposes to require state boards and agencies to accept the services of **licensed optometrists** for any service covered by their licenses on the same basis and on a parity with any other person authorized by law to render similar professional service.

GOVERNMENT SERVICES

ARMY

THE ARMY NEEDS SPECIALISTS

Specialists to fulfil current requirements of the Army Medical Department are needed in all fields. In the fields of allergy, cardiology, gastroenterology, pulmonary diseases and neurosurgery the Army does not have a board-certified specialist, although officers in each of these fields are in training for certification by these boards. Commissions in the Medical Corps, both regular and reserve up to and including the rank of lieutenant colonel, are available in these fields for qualified civilian physicians depending on length of experience. As of January 25, the Medical Department had 143 regular officers and 10 civilian component officers on active duty who were certified by American specialty boards. This is an increase of 51 from the date of the last published survey, Sept. 1, 1947.

THE HOSPITAL AT SAULT SAINTE MARIE

Since September 1944, the former army station hospital at Sault Sainte Marie, Mich., has been in use as a state mental institution. As the lease held by the state expires next September, a conference was held February 8, with the Assistant Secretary of the Army, Gordon Gray, the Governor of Michigan, G. Mennen Williams, Senator Homer Ferguson, Representative Charles E. Potter, several Michigan state legislators and other representatives of the State of Michigan. The Assistant Secretary of the Army assured the Michigan delegation that he will do what he can under established budgetary procedures to put the Army in a position to construct a permanent installation at Sault Sainte Marie. This, he believed, is the solution to the long range problem, but funds are not now available for such construction. The State of Michigan needs to retain the hospital for use by its mental patients, at least temporarily.

DISTRIBUTION OF THE INDEX-CATALOGUE

The Army Medical Library reports that the distribution of the five volumes of the Index-Catalogue of the Surgeon-General's Office published during the war years has been completed, except for a few libraries in Germany, mostly in the Russian Zone, and a few other libraries. Remarkably few sets of the Index-Catalogue were completely destroyed during the war. Lost entirely were those in the Philippine Islands, Torino, Karlsruhe, Kiel, Münster, Munich and some of those in Berlin; partially lost were the sets in Amsterdam, Freiburg im Breisgau and some other libraries.

NURSE CORPS CELEBRATES FORTY-EIGHTH ANNIVERSARY

On February 2 the Army Nurse Corps celebrated its forty-eighth anniversary as part of the United States Army.

The Surgeon General, Major General Raymond W. Bliss, said that with the passing of the years, each of the ten surgeons general who have served the Medical Department since the Army Nurse Corps was established has found increasing value in the contributions made by women in the Medical Department. "First, we had only nurses, then we included dietitians, then physical therapists and now occupational therapists. Ours is a medical team, but because of the sincere efforts of the Army Nurse Corps through the years, we are including more and more women in our fold."

General Lucias D. Clay, Commander in Chief, European Command, said, "Army nurses in Normandy went in directly behind the first wave of assault troops to land in France. They waded ashore June 6, 1944, a few hours after the invasion, and set up dressing stations in pup tents on the beach where they ministered to the wounded. The world remembers the valor and courage of the Army nurses who served on Bataan and Corregidor."

General Omar N. Bradley, Chief of Staff, said, "In our effort to make the Army a better place to live and work, with greater understanding in its relationships, with a more selfless devotion to our duty and our fellow soldiers, we can take as an example the accomplishments of the nurses who have served with the Army throughout the world, in peace and war, for so many years."

General Douglas MacArthur, Commander in Chief of the Far East Command, from Tokyo sent a message saying, "I join with all ranks of commands in grateful tribute to the 48 years of devoted national service the Army Nurse Corps has rendered in ministering to sick and wounded. In war and in peace—through the grim ordeal of battle and the lull which has followed—it has built a noble tradition of service, sacrifice and valor."

General Jacob L. Devers, Chief, Army Field Forces, said, "The thousands of World War II Army Nurses who served nobly with the Ground Force combat units overseas, enduring the hardships and dangers, . . . were a constant source of inspiration to the fighting men who knew that you were helping to give them the best medical care that this nation could provide."

INDEX COMMITTEE MEETING

The Committee of Consultants for the Study of Medical Indexing held its third meeting January 14, in the Library of Congress, Washington, D. C. The following working subcommittees were formed from the main committee: Need for Medical Indexes, Dr. Chauncey D. Leake, chairman; Use of Medical Indexes, Miss Janet Doe, chairman; Scope and Coverage of Medical Indexes, Dr. John F. Fulton, chairman, and Techniques in Indexing, Dr. Mortimer Taube, chairman. The Committee will hold its next meeting March 11.

ACCEPTED FOR ADVANCED TRAINING

The following Medical Corps officers have been accepted for advanced classes in civilian schools and hospitals indicated:

Name and Rank	Institution	Course
Frank A. Mantz, Major	Massachusetts General Hospital, Boston	Fellowship in pathology
Edwin J. Pulaski, Major	Oak Ridge Institute of Nuclear Studies, Oak Ridge, Tenn.	Radioisotope technics
John W. Braasch, First Lieut.	Oak Ridge Institute of Nuclear Studies, Oak Ridge, Tenn.	Radioisotope technics
Robert F. Newton, First Lieut.	Hartford Hospital, Hartford, Conn.	Residency in pediatrics
John M. Cahill, First Lieut.	Boston City Hospital, Boston	Residency in surgery
James B. Elkins, First Lieut.	Alexandria Hospital, Alexandria, Va.	Assistant resident in obstetrics
Jose Cerra-Quinones, First Lieut.	Graduate School of Medicine, University of Pennsylvania, Philadelphia	Postgraduate course in obstetrics and gynecology
Alan I. Blumberg, First Lieut.	Jewish Hospital, Philadelphia	Residency in pathology
Robert G. Gildersleeve, First Lieut.	South Baltimore General Hospital, Baltimore	Residency in general surgery
Donald J. Caseley, First Lieut.	Indiana University Medical Center, Indianapolis	Intern training
John F. McGarry, First Lieut.	Ball Memorial Hospital, Muncie, Ind.	Intern training
Anthony J. Puglisi, First Lieut.	Grasslands Hospital, Valhalla, N. Y.	Intern training

NAVY

EXAMINATIONS FOR APPOINTMENT IN MEDICAL CORPS

Examinations for the selection of candidates for appointment to the grade of lieutenant (junior grade) in the Medical Corps of the Navy will be conducted at all Naval hospitals in the United States, April 4-8, 1949. Graduates of approved medical schools in the United States or Canada who have completed intern training in accredited hospitals or who will complete such training within four months of the date of the examination, and who are physically and otherwise qualified, may be examined for appointment if less than 32 years of age. They will be required to appear before boards of medical examiners and supervisory Naval examining boards at the Naval hospital nearest their residence. Following approval by the President of the United States and confirmation by the Senate, selected candidates will be issued appointment and orders assigning them to active duty. As a result of the authorized additional compensation of $100 a month for medical officers, a lieutenant (junior grade) in the Navy Medical Corps receives pay and allowances totaling $5,011 a year if married and $4,575.50 if without dependents. Information concerning the procedure of application may be obtained from the nearest Naval Officers Procurement Office or from the Bureau of Medicine and Surgery, Navy Department, Washington 25, D. C. (Attn: Code-3424).

FIRST ACTIVE DUTY AS INTERNS

The following lieutenants (jg) in the Medical Corps Reserve have been ordered to their first active duty as interns in civilian institutions under the Navy's graduate medical training program:

Name	Residence	Institution
Barth, Robert L.	New Washington, Ohio	Indianapolis General Hospital, Indianapolis
Bartzen, Peter J.	Milwaukee	Milwaukee County Hospital
Beaven, William E.	Rochester, N. Y.	Union Memorial Hospital, Baltimore
Berry, Paul T.	St. Louis	St. Luke's Hospital, St. Louis
Foster, Claude F., Jr.	Oklahoma City	St. Anthony Hospital, Oklahoma City
Herring, Edwin B.	Dundee, Miss.	John Gaston Hospital, Memphis, Tenn.
Maxson, Eugene S.	Alhambra, Calif.	Glendale Sanitarium and Hospital, Glendale, Calif.
McKelvey, Joseph S.	Bellaire, Ohio	University of Pittsburgh Medical Center
McKinney, James E.	Atlanta, Ga.	Charity Hospital of Louisiana, New Orleans
Montgomery, Wayne S.	Detroit	Harper Hospital, Detroit
Rholl, Arnold O.	Minneapolis	Northwestern Hospital, Minneapolis
Rogers, Malcolm E.	Gilbertown, Ala.	Naval Hospital, Portsmouth, Va.
Simpson, Arthur M.	Toledo, Ohio	Wesley Memorial Hospital, Chicago
Stone, Bernard B.	Revere, Mass.	Worcester City Hospital, Worcester, Mass.
Taylor, Clayton B.	Madera, Calif.	General Hospital of Fresno County, Fresno, Calif.
Walzer, Mackenzie	Darien, Conn.	Massachusetts General Hospital, Boston
Wilkinson, Ernest L.		Johns Hopkins Hospital, Baltimore

MEDICAL ASPECTS OF SPECIAL WEAPONS AND RADIOACTIVE ISOTOPES

One hundred and seventy-five Naval reserve medical officers comprised the second class for the five day course in medical aspects of special weapons and radioactive isotopes, which convened at the Naval Medical School, Bethesda, Md., February 14. In addition to speakers from the Naval Medical Center, the instructors comprised representatives from the Atomic Energy Commission, U. S. Public Health Service and the following civilian scientists: George Gamow, Howard Andrews, J. B. Trunnell, C. F. Geschickter, Herbert Friedman, L. D. Fothergill, Francis Gordon, Leslie Chambers, Philip H. Abelson, Shields Warren and William F. Sullivan.

POSTGRADUATE INSTRUCTION

The following medical officers have been nominated for postgraduate instruction in residencies at the institutions indicated: Comdr. Earl J. Palmberg of Red Oak, Iowa, ophthalmology, Naval Hospital, San Diego, Calif.; Lieutenants (jg) Edward Martin Jr. of Boston, anesthesiology, Naval Hospital, Chelsea, Mass.; Anthony P. Prezyna of Lackawanna, N. Y., pathology, Naval Hospital, Bethesda, Md., and Charles E. Rogers of Milwaukee, surgery, Naval Hospital, St. Albans, Long Island, New York.

Comdr. David Singer of San Diego, Calif., and Lieut. Edward D'Orazio of Steubenville, Ohio, both reserve officers, have been voluntarily recalled to active duty to receive postgraduate instruction under the Graduate Medical Training Program as residents in internal medicine and pediatrics at the Naval Hospital, Long Beach, Calif., and the Naval Hospital, Chelsea, Mass., respectively.

NEW REGULAR OFFICERS

The following medical officers have transferred from an active reserve status to the Medical Corps of the Regular Navy: Commander Charles A. Castle of Watertown, South Dakota; Commander Berger Thomas of Columbus, Ohio; Lieutenants (jg) Benjamin F. Burns of Pasadena, Calif.; Harold W. Garvin of Mascoutah, Ill.; Albert M. Jenkins of Norwood, Ohio, and Stuart D. Kustermann of Minneapolis.

RESERVE OFFICERS ON ACTIVE DUTY

The following reserve medical officers have voluntarily been recalled to active duty: Capt. Edwin C. Swift of Jacksonville, Fla.; Comdr. Wilbur W. Westfall of Somerset, Pa., and Lieut. Comdr. Meshel Rice of Detroit.

Comdr. Jacob G. Hebble and Lieut. Bruce H. Smith Jr. have been nominated for courses in postgraduate instruction at the Illinois Neuro-Psychiatric Institute, Chicago, and the New England Deaconess Hospital, Boston, respectively.

VETERANS ADMINISTRATION

MILLIONS OF PRESCRIPTIONS

During 1948, some 4,000,000 prescriptions for veteran-patients were filled by privately owned pharmacies and those operated by the Veterans Administration. According to E. Burns Geiger, chief, pharmacy division of the Veterans Administration, about 500,000 of these prescriptions were filled by 25,000 privately operated pharmacies throughout the country which take part in the Veterans Administration home town pharmacy program, while the remaining 3,500,000 prescriptions were filled by 333 pharmacists in Veterans Administration hospitals, homes and regional offices. Private pharmacists have been authorized under agreement between the Veterans Administration and the state pharmaceutic associations in forty-six states, the District of Columbia and Hawaii, to fill prescriptions at government expense for veterans undergoing outpatient treatment for a service-connected ailment.

PERSONAL

The new director of the Veterans Administration Library Service is Foster E. Mohrhardt, formerly associate professor of library science at Columbia University and librarian at Washington and Lee University. Mr. Mohrhardt, a native of Michigan, succeeds Francis R. St. John, who resigned December 17 to become affiliated with the Brooklyn public library.

Dr. James S. Cullyford, chief of medical services in the regional office in Denver, was recently decorated by the Netherlands Government for outstanding service to the Dutch people held in German concentration camps during the war. Dr. Cullyford served with the Twelfth Army Group in Europe after D-Day as public health officer in the civil affairs section and was responsible for the medical care of inmates in certain prison camps.

PUBLIC HEALTH SERVICE

CONFERENCE ON TUBERCULIN AND HISTOPLASMIN SENSITIVITY

A conference was held February 2-3 in Washington, D. C., at the invitation of the Division of Tuberculosis of the Public Health Service, to consider the prevalence of tuberculin and histoplasmin skin sensitivity among young adults. In addition to the staff of the Field Studies Branch of the Division of Tuberculosis, the following persons attended the conference: Drs. Ralph I. Canuteson, University of Kansas; L. M. C. Luykx, New York University; John A. Prior, Ohio State University; Comdr. R. O. Canada, U. S. N., Washington, D. C.; Drs. G. A. Cronk, Syracuse University; J. A. Meyers, University of Minnesota; Max L. Durfee, Miami University, Oxford, Ohio; W. G. Beadenkopf, University of Chicago, and Capt. Samuel Saslaw, M. C. A. U. S.

The conference indorsed the proposal of the chief of the branch, Dr. Carroll E. Palmer, that steps be taken to organize a broad study of the distribution of tuberculin and histoplasmin sensitivity among young adults in the United States through skin tests and roentgen examinations of university and college students.

DR. HARRISON TO RETIRE

Dr. Walter T. Harrison, for many years a commissioned officer in the Public Health Service, is now on terminal leave and will retire from the service on July 1. Dr. Harrison was first commissioned in the U. S. Public Health Service in 1916. Among his many important assignments was service at the Hygienic Laboratory, Washington, D. C., the predecessor of the National Institutes of Health, where he carried on research on diphtheria immunization. His last assignment has been medical director for Region 10, which includes Arizona, California, Nevada, Oregon, Washington, Alaska and Hawaii. Dr. Harrison also was a member of the Permanent Commission on Biological Standardization of the health organization of the League of Nations. In 1937 he lectured at Vanderbilt University School of Medicine, Nashville, Tenn., on immunology and the use of biologic products.

NEW SECTION ON EXPERIMENTAL THERAPEUTICS

Surgeon General Scheele has announced the appointment of Dr. Harry Eagle as chief of the new Experimental Therapeutic Section in the National Institutes of Health; other personnel in the new section include many of the research men who were associated with Dr. Eagle when he was director of the Laboratory of Experimental Therapeutics, a joint project of the Public Health Service and the Johns Hopkins School of Hygiene. In order to devote full time to this field, Dr. Eagle will relinquish his position as scientific director of the National Cancer Institute, where he has been in charge of research activities since July 1947.

MISCELLANEOUS

SEMINAR ON DISPOSAL OF RADIOACTIVE WASTES

A two day seminar on disposal of radioactive wastes sponsored by the United States Atomic Energy Commission was held in Washington, D. C., January 24-25. In discussing health problems in atomic energy activities, Dr. Shields Warren, director, division of biology and medicine of the Atomic Energy Commission, said it is possible to detect radioactivity at levels far below those dangerous to human beings and that the problems dealt with are not unknown hazards. The prime objective of the radioactive waste disposal program is to prevent radioactive materials from being absorbed by human bodies, and, to the best of his knowledge, the precautions being used at atomic energy sites are giving adequate protection.

Dr. Austin Brues, director of biology and medicine at the Argonne National Laboratory, Chicago, said that in the matter of external total body radiation, the standardized tolerance level is 0.1 r per day. This applies to persons exposed to radiation continuously, day in and day out. Persons who do not receive continuous exposure can tolerate single doses of radiation of many roentgens without detectable damage, and for certain pathologic conditions radiation treatment requires doses far beyond any that can be tolerated normally.

The director of engineering, Roger S. Warner, and Arthur V. Peterson of the production division of the Atomic Energy Commission said that the low permissible limits for radioactivity discharged into soil, air or water are usually met through technics of dispersion and dilution and use of normal industrial decontaminating devices, such as filters and scrubbers. The high level wastes produced at the great atomic energy production centers are held at the site until the radioactivity decays, and this material is held indefinitely or is reprocessed for its highly valuable components.

The director of the Health Physics Division, Oak Ridge, Tenn., National Laboratory, Dr. Karl Z. Morgan, said that after the radioactive wastes from the plants at Oak Ridge were discharged into the Clinch River the level of radioactivity in the river was considerably less than that in many of the mineral waters widely used in the United States for drinking purposes, and that the amount of radioactivity contributed from all Oak Ridge operations to the atmosphere of the neighboring area is less than the added cosmic radiation exposure one receives in going from sea level to Denver at 5,000 feet elevation.

Dr. C. C. Ruchhoft of the United States Public Health Service discussed the possibilities of developing concentration methods for radioactive liquid waste treatment by biologic processes similar to those now used in sewage treatment, which possibilities, he said, appear promising.

Dr. Abel Wolman, director, Department of Sanitary Engineering, Johns Hopkins University, Baltimore, predicted that the sanitary engineer and the water and sewage plant operators in the future will take on the function of protecting the water supply and the atmosphere of communities against the hazards of contamination by radioactive wastes, just as they now protect communities against air and water pollution. He said that it was necessary for sanitarians to begin at once to learn the new words associated with radioactive wastes and to become acquainted with the instruments used to measure the degrees of radioactivity.

LAWRENCE HAFSTAD MADE DIRECTOR OF REACTOR DEVELOPMENT DIVISION

The U. S. Atomic Energy Commission has appointed Dr. Lawrence R. Hafstad as Director of the Reactor Development Division. It is principally through the development of reactors that the commission expects in coming years to develop a means for utilizing the energy released by nuclear fission.

Dr. Hafstad has been on leave of absence from Johns Hopkins University, where he is Director of Research of the Applied Physics Laboratory at Silver Spring, Md., in which laboratory he helped perform much of the work leading to development of the proximity fuse. His duties with the Atomic Energy Commission include responsibility to General Manager Carroll L. Wilson for the activities of the Chicago Operations Office, which gives administrative support to the Argonne National Laboratory, the center of reactor development, and the program at Knolls Atomic Power Laboratory at Schenectady, N. Y.

Dr. Hafstad was born in Minneapolis and was graduated from the University of Minnesota in 1926; since July 1, 1948, he has been executive secretary of the Research and Development Board, in which position his successor will be Robert F. Rinehart, since July 1, 1948 director of the Board's planning division.

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

CALIFORNIA

Public Lectures at Stanford.—Stanford University School of Medicine is presenting its sixty-seventh course of Popular Medical Lectures by members of its faculty at Lane Hall in San Francisco, Wednesday evenings at 8 p. m.:

March 30, Roy B. Cohn and Herbert N. Hultgren, Diagnosis and Treatment of Congenital Heart Disease.
April 6, Charles E. McLennan, Cancer of the Uterus.
April 20, William McD. Hammon, Poliomyelitis: Means of Spread and Control.
April 27, Alfred E. Maumenee Jr., San Francisco, Prevention and Treatment of Blindness in Childhood.

Dr. John A. Anderson to Head Pediatric Department.—Dr. John A. Anderson, professor and chairman of the department of pediatrics and communicable diseases at the University of Utah College of Medicine, Salt Lake City, will join the faculty of the Stanford University School of Medicine, Stanford University-San Francisco, September 1, succeeding Dr. Harold K. Faber as professor and head of the pediatrics department. Dr. Faber becomes professor emeritus in September.. Dr. Anderson received his M.D. in 1933 and his Ph.D. in 1940 at the University of Minnesota. He interned at Minneapolis General Hospital 1933-1934 and the following year was a research assistant in pediatrics. After two years as a Commonwealth Club Fellow of the Child Research Council in Denver, he rejoined the Minnesota Medical School faculty in 1937; he accepted the pediatrics post at Utah in 1943.

COLORADO

Institute on Epilepsy.—The First Western Institute on Epilepsy will meet at the University of Colorado Medical Center, Denver, May 16-18. Members of the medical profession, social workers, psychologists and interested laymen are invited. Lectures, clinics and round table discussions will be held. Dr. Jerry Price of the Neurological Institute, New York, will be the keynote speaker. Institute fees will be $5. For information address the Director, Epilepsy Service, University of Colorado Medical Center, Denver.

Fellowship in Industrial Medicine.—The University of Colorado Medical Center, Denver, is offering a three year fellowship in industrial medicine. The course will give advanced training in industrial medicine leading to the degree Doctor of Industrial Medicine. The stipends will be $1,800 and $2,400 for the first and second years respectively. Appointments are made January 1 and July 1. This course is approved by the Veterans Administration for candidates who are eligible under the G. I. Bill of Rights. The first two years will consist of didactic work. Time and facilities for research will be provided, and a thesis will be required. The third year will be spent in training in industry under supervision. The stipend for this year will be announced later. Requirements include graduation from an approved medical school, at least one year of internship training, and preferably at least one year of residency training in one of the specialties or one or more years of practice of medicine. For further information write Frank Princi, M.D., Director, Division of Industrial Medicine, University of Colorado Medical Center, Denver.

FLORIDA

Annual State Medical Meeting.—The Florida Medical Association will hold its annual meeting at Belleair with headquarters at the Belleview-Biltmore Hotel April 11-13, under the presidency of Dr. Joseph S. Stewart, Miami. Visiting speakers will be:

Clarence G. Bandler, New York, Hematuria; Its Clinical Significance.
Michael L. Mason, Chicago, Early Closure of Burned Areas.
Frederick H. Falls, Chicago, Management of Eclamptogenic Toxemia.
Cushman D. Haagensen, New York, Diagnosis of Cancer of the Breast.

The Women's Auxiliary to the state association and a number of specialty groups will also meet at this time.

GEORGIA

Course for General Practitioners.—The University of Georgia School of Medicine, Augusta, in cooperation with the Medical Association of Georgia will give a postgraduate course in medicine and surgery for general practitioners April 11-15 designed to present current ideas concerning the diagnostic and therapeutic problems of general practice. The enrolment is limited, and the registration fee of $15 includes the cost of five luncheons. For information address Director of Postgraduate Education, University of Georgia School of Medicine, University Place, Augusta.

ILLINOIS

Postgraduate Conferences.—The Postgraduate Education Committee of the Illinois State Medical Society has arranged a postgraduate conference for the Second Councilor District March 31 at the Kaskaskia Hotel, La Salle. The district includes Bureau, La Salle, Lee, Livingston, Marshall, Putnam, Whiteside and Woodford counties. On the program, beginning at 1:30 p. m., the following Chicago physicians will speak:

Arkell M. Vaughn, Vagotomy in Treatment of Gastro-Intestinal Ulceration.
Harry M. Hedge, Birthmarks.
Henry G. Poncher, Practical Aspects of Pediatric Therapy.
Chauncey C. Maher, Combination of Gallbladder Disease and Coronary Disease.
Frederick H. Falls, Early Diagnosis of Carcinoma of the Uterus.

There will be a round table discussion from 5 to 5:30 p. m. The dinner speaker will be Dr. Percy E. Hopkins, Chicago, president of the Illinois State Medical Society, on "Voluntary Prepayment Medical and Surgical Care."——A postgraduate conference for the Tenth Councilor District will be held at the Elks Club Du Quoin, April 7, with the following participants:

Kilian F. Fritsch, East St. Louis, Rehabilitation of Victims of Poliomyelitis.
Edward H. Reinhard, St. Louis, Diagnosis and Treatment of Hemorrhagic Disorders.
G. Lynn Krause, St. Louis, Diagnosis and Surgical Treatment of Polypi in the Large Intestine in Infants and Children.
Willard O. Thompson, Chicago, Diseases of the Adrenals.
Harry M. Hedge, Chicago, Birthmarks.

In the evening, Dr. Walter Stevenson, Quincy, will discuss "Crossed Eyes—A Medical and Economic Problem." The Tenth Councilor District comprises Alexander, Jackson, Monroe, Perry, Pulaski, Randolph, St. Clair, Union and Washington counties.

Chicago

Medical Genetics Lectures.—Eight medical lectures on subjects pertaining to human genetics will be given Tuesday evenings at 8 p. m. in Room M-137, Albert Merritt Billings Hospital, from March 29 to May 17. The lectures, open to any one interested, will be delivered with the exception of that of May 10, by Herley H. Strandskov, Ph.D., associate professor of zoology, at the University of Chicago. The schedule is as follows:

March 29, Human Chromosomes; General Genetic Principles; M-N Blood Types; Sickle Cell Anemia.
April 5, Genetics of the A-B Blood Groups.
April 12, Recent Views on the Genetics of the Rh-Hr Blood Factors.
April 19, Role of Heredity in the Etiology of Cancer.
April 26, Genetics and Variations in Mental Characteristics.
May 3, Genetics of Human Populations.
May 10, Robert D. Boche, Ph.D., Chicago, Radiation and Genetics.
May 17, Genetics and Medicolegal Problems.

Northwestern's Faculty and Alumni Reunion.—The annual medical faculty-alumni reunion dinner of Northwestern University Medical School will be held at 6 p. m. May 14, in the Lake Shore Club. Dr. J. Roscoe Miller, retiring dean of the school who will become president of the university in July, will be the guest of honor. The principal speaker will be Dr. Frederick W. Merrifield, a member of the surgery faculties of the medical and dental schools. Representatives of the five-year medical classes of 1904, 1909, 1914, 1919, 1924, 1929, 1934, 1939 and 1944 will have special tables at the dinner, and members of the classes of 1894 and 1899 and this year's graduating class will be guests of the medical alumni association. Reservations may be made through the office of the association, Room 796, Montgomery Ward Building, 303 E. Chicago Avenue, Chicago.

INDIANA

Courses in Roentgenology and Micology.—A course in basic roentgenographic procedure for technicians attached to laboratories of physicians and hospitals will be offered by Purdue University, Lafayette, in cooperation with the General Electric X-Ray Corporation April 4-8. Classes will be held from 1-5 p. m. to accommodate commuting students. J. B. Thomas of the General Electric X-Ray Corporation will be the instructor; other members of the staff will be Dr. Donald C. McClelland and H. George DeKay, Ph.D.

The Industrial Micology Course will be held July 11-23. The afternoon sessions will be devoted to a course in "Physiology of the Fungi." Special evening lectures by practicing industrial micologists will be announced later. Information may be obtained from Merle M. McClure, Coordinator of Adult Education, Technical Extension Division, Purdue University, Lafayette.

KANSAS

Two Postgraduate Courses.—The School of Medicine of the University of Kansas and the Kansas Medical Society have arranged a postgraduate course in anesthesiology April 4-6 at the university in Kansas City. While arranged especially for doctors in practice in Kansas, the course is open to all doctors of medicine. The fee is $20. Guest faculty members include: Drs. Henry K. Beecher, Boston; L. Lafe Bresette, Kansas City; M. Digby Leigh, Vancouver, B. C.; Richard S. McKee, Wadsworth; Stevens J. Martin, Hartford, Conn.; Merritt H. Kimball, Hugh S. Mathewson, Milton C. Peterson, Louis Porter, and Charles H. White, all of Kansas City, Mo.; Floyd C. Taggart, Topeka, and Rolland J. Whitacre, Cleveland.

A postgraduate course in internal medicine, psychiatry and dermatology will be presented March 28-31 at the university in cooperation with the state medical society and the Kansas State Board of Health. Besides members from the University of Kansas, instructors include Drs. Mandred W. Comfort, Rochester, Minn.; John M. Lyon, Denver; Elmer L. Sevringhaus, Nutley, N. J., and Cecil J. Watson, Minneapolis. The program includes a panel discussion in endocrinology. The fee is $25. For registration, address Extension Program in Medicine, University of Kansas Medical Center, Kansas City 3.

KENTUCKY

The Alben W. Barkley Chair of Medicine.—At the University of Louisville School of Medicine a professorship has been established for research into heart diseases to be designated "The Alben W. Barkley Chair of Medicine." Dr. John Walker Moore on his retirement as dean of the Medical School July 1 will assume the professorship. Funds for the first phase of the project will be provided by Vice President Barkley's gift to the university of the $10,000 Collier's Magazine Award which he received last year for distinguished public service. The money is to be used for research in heart disease, from which the Vice President's wife died two years ago. Mr. Barkley stated that he hoped the fund will be increased from other sources until it becomes a substantial foundation for research into heart diseases.

LOUISIANA

Establish Department of Psychiatry and Neurology.—A department of psychiatry and neurology has been established at Tulane University of Louisiana School of Medicine, New Orleans. Dr. Robert G. Heath, formerly of the Neurological Institute, New York, and the psychoanalytical clinic of the Columbia University College of Physicians and Surgeons, will head the department. Facilities will be correlated with community agencies in the New Orleans area, especially those of the social services unit. Graduate training consists of a three year training program for approved physicians in neurology or psychiatry, with psychoanalytical training optional through the New Orleans psychoanalytical group. Research is directed toward coordination between physiologic-biophysical factors in behavior and investigations of local cultural factors. The medical curriculum on the undergraduate level has been expanded to include more courses in neurology and psychiatry.

MASSACHUSETTS

Dunham Lectures.—The Edward K. Dunham Lectures for the Promotion of the Medical Sciences will be presented at the Harvard Medical School, Boston, in the Amphitheater, Building D, by Dr. Wilder G. Penfield, professor of neurology and neurosurgery, McGill University, Montreal, Canada, on "The Cerebral Cortex of Man." The first lecture, "Localization of Function," will be given March 28; on March 30 the subject will be "Ictus Epilepticus (Physiological Observations on the Mechanism of Cerebral Seizures)," and on April 1 "The Anatomy of Hallucinations, Dreams and Memory."

MICHIGAN

Marshall Memorial.—A four bed room at Hurley Hospital, Flint, will be furnished by funds raised as a memorial to Dr. William H. Marshall, Flint, who died Jan. 8, 1948. Funds were collected by a memorial committee of laymen and physicians to establish a project of community and cultural value.

Undergraduate Psychiatric Training.—The U. S. Public Health Service has made a grant of $37,500 to further development of the undergraduate psychiatric training program in Wayne University College of Medicine, Detroit. The fund is to be expended over a three year period in supplementing facilities now available. Dr. John M. Dorsey, chairman of the department of psychiatry, will be in charge of the program.

Sixteenth Annual Clinic.—The West Side Medical Society of Detroit will hold its sixteenth annual clinic May 4 from 10 a. m. to 4 p. m. in the auditorium of the Wayne County General Hospital and Infirmary at Eloise. The following program will be presented:

Clarence E. Umphrey, Detroit, Reactions to New Legislation Proposed by Medicine, Labor and Federal Security.
Edward J. McCormick, Toledo, Can the American Doctor Save Private Enterprise?
Bradley M. Patten, Ph.D., Ann Arbor, Micromoving Picture Records of the First Beats of the Embryonic Heart.
F. William Sunderman, Cleveland, Electrolytes in Health and Disease.
Philip Thorek, Chicago, Intestinal Obstruction.
Thomas L. Pool, Rochester, Minn., Tuberculosis of the Urinary Tract.
Walter S. Priest, Chicago, Management of Patients with Coronary Artery Disease.

There will be no registration fee, and all physicians are invited.

MINNESOTA

Communicable Diseases—New Low Records.—The Minnesota Department of Health reports that compared with the preceding year, 1948 was especially free from communicable diseases. Pneumonia reached a low level of 1,009 deaths compared with a previous low in 1946 of over 1,100 deaths. The 64 influenza deaths in 1948, which were fewer than half the number reported for 1947, also established a new low. Deaths from tuberculosis numbered 503, setting a new all-time low. There were 4 deaths among 28 cases of typhoid reported in 1948 compared with 5 deaths from this disease during the period 1944-1947 inclusive. No case of smallpox was reported in the state during the year; the last death from the disease occurred in 1941. Deaths from diseases most common in childhood include 15 from diphtheria, 14 from whooping cough, 11 from measles and 3 from scarlet fever.

NEW HAMPSHIRE

Personal.—Dr. George H. Stueck Jr., formerly of New York, has been appointed assistant professor of clinical medicine and assistant professor in the physiological sciences at Dartmouth Medical School, Hanover. He was also appointed to the medical staff of the Veterans Administration Hospital, White River Junction, Vt., as chief of research and assistant chief of medicine. Following his four years in the Army Medical Department during the recent war, Dr. Stueck returned to New York and was appointed lecturer in biochemistry and assistant in medicine on the staff of New York University College of Medicine.

NEW JERSEY

Oxford Professor to Lecture.—Dr. Leslie Witts, Nuffield professor of clinical medicine at Oxford University, England, will speak at the Ventnor Clinic staff meeting May 4 at Haddon Hall, Atlantic City, 9 p. m. on "The Teaching Hospital and the National Health Service." Dr. Witts will also act as visiting chief at the Atlantic City Hospital May 2-7.

NEW YORK

Edward J. Meyer Laboratory.—Mrs. S. Margaret Meyer has bequeathed $432,454.57 to construct, equip and maintain a research laboratory at the University of Buffalo Medical School. The institution will be known as the Edward J. Meyer Laboratory in memory of her husband, a Buffalo physician. Dr. Meyer died in September 1935.

Postgraduate Lectures.—The state medical society in cooperation with the state health department has arranged a series of lectures for the Saratoga County Medical Society to be given at the Saratoga Hospital, Saratoga Springs, at 3 p. m.

March 30, Nathan Sobel, New York, Diagnosis and Treatment of Common Skin Diseases.
April 6, Leon G. Berman, New York, Diagnosis and Treatment of the Acute Abdomen.

The Cayuga County Medical Society meeting at 8 p. m. at the Springside Inn, Auburn, will hear Dr. Ferdinand J. Schoeneck, Syracuse, speak on sterility.

New York City

A Death from Chickenpox.—There were 2,060 cases of chickenpox reported to the New York City Department of Health in February and 1,389 cases reported in January, the largest number of cases since April 1947. One death from chickenpox was also reported in January but none in February.

Course in Surgical Anatomy.—A course in surgical anatomy will be given at the Cornell University Medical College June 1-30 for five and one-half days a week, designed especially for candidates for the American Board of Surgery. The course will consist of an intensive review of surgical anatomy with demonstratio [illegible] Dr. Ernest W. Lampe will be in charge. [illegible] to 25, and the fee is $200. Inquiries may be directed to the Office of the Dean, Cornell University Medical College, 1300 York Avenue, New York 21.

Institute of Industrial Medicine Course.—The Institute of Industrial Medicine of the New York University-Bellevue Medical Center on March 3 inaugurated a course in medicine in industry for third year students at the New York University College of Medicine. Extending over a period of 12 weeks, the course will include lectures in dust diseases, lead, solvents, dermatoses, psychiatry in industry, applied physiology of respiration as applied to dust diseases, organization and administration of industrial medical departments, physical factors in the industrial environment, the role of research and physical examinations. Dr. Anthony J. Lanza is chairman of the institute.

Chest Surgery on Lower East Side.—The Lower East Side Planning Council, which includes fourteen settlement houses, churches and other organizations, in cooperation with the City of New York Department of Health is conducting a one month free mass chest roentgenologic survey on the Lower East Side. The campaign opened March 8. Tuberculosis occurs more frequently in the Lower East Side than in most other parts of the city, it is reported. Of all thirty health center districts in New York City, the Lower East Side has the second highest number of tuberculosis deaths as well as the second highest number of newly reported cases of tuberculosis. In about 10 per cent of all new active cases of tuberculosis which have come to the attention of the Health Department during the past year the patients are residents of the Lower East Side Health Center District.

OHIO

Annual State Medical Meeting.—The Ohio State Medical Association will hold its annual session April 19-22 with headquarters at the Neil House, Columbus. Section meetings will be from 9 a. m. to noon. Out of state speakers include:

Charles S. Cameron, New York, Cancer Control.
Joseph W. Gale, Madison, Wis., The Crippled Lung.
Henry S. Ruth, Philadelphia, Anesthesiology as an Aid to Diagnosis and Treatment.
Kenneth E. Appel, Philadelphia, Psychiatric Aspects of Medicine.
Philip M. Stimson, New York, Diagnosis and Treatment of Early Poliomyelitis.
John R. Neefe, Philadelphia, Recent Developments in Viral Hepatitis and Other Liver Diseases.

On Wednesday afternoon five groups will discuss the most recent developments in medicine and surgery. On Friday morning six round table discussions will include problems most frequently encountered by physicians. Both these programs are innovations in the annual session. Eighteen instructional courses following the line of panel discussions, designed to provide practical instruction on handling clinical problems, will be presented during the mornings Tuesday through Thursday. Attendance will be limited and admission will be by ticket only. Thursday evening's program will be devoted to a question and answer session on the procedures of the state's Industrial Commission, Department of Public Welfare and Department of Health.

The annual banquet will be held Wednesday at 7:30 p. m. The Woman's Auxiliary will meet at the Seneca Hotel April 19-21. Special societies holding meetings include the Ohio State Radiological Society and the Ohio chapters of the American College of Chest Physicians and the Academy of General Practice.

PENNSYLVANIA

Report of State Cancer Coordinating Committee.—The Pennsylvania State Cancer Coordinating Committee, made up of representatives of leading cancer fighting agencies in the state, has released its first report which indicates the wide scope of the cancer program in Pennsylvania. Organizations included in the committee are the Commission on Cancer of the Medical Society of the State of Pennsylvania, the Division of Cancer Control of the State Department of Health and the Pennsylvania and Philadelphia divisions of the American Cancer Society. The primary function of the committee is to prevent overlapping of programs through planned allocation of the functions or primary objectives of each agency. The problems with which the committee is concerned include lay and professional education, diagnosis and treatment of cancer, statistical and research organizations, organization and campaigns for funds. Specific phases of each of these problems have been assigned to participating agencies, and a substantial measure of cooperation on the part of each is reported. Members of the committee are Drs. John V. Blady, Philadelphia, and Horace B. Anderson, Johnstown, for the state medical society; Ross M. Vickers, Williamsport, and Dr. Harold J. Harris, Wilkes-Barre, for the Pennsylvania Division of the American Cancer Society, and Dr. Catharine Macfarlane, and E. C. Nicodemus for the Philadelphia Division of the American Cancer Society. Dr. Leverett D. Bristol, chief of the Division of Cancer Control of the Pennsylvania Division of Public Health, is chairman.

Philadelphia

Lecture on Cancer Chemotherapy.—Morris Belkin, Ph.D., National Cancer Institute, Bethesda, Md., will speak on "Current Experimental and Clinical Cancer Chemotherapy" April 8 at 8 p. m. in the Assembly Hall of Jefferson Medical College of Philadelphia. This is the annual lecture of the college chapter of Phi Lambda Kappa. All are invited to attend.

Appoint Director of Johnson Foundation.—Britton Chance, Ph.D., has been appointed director of the Eldridge Reeves Johnson Foundation for Medical Physics of the University of Pennsylvania School of Medicine. Dr. Chance, who before his appointment was associate professor of biophysics in the university's medical school, succeeds Dr. Detlev W. Bronk, who in January became president of Johns Hopkins University, Baltimore. Dr. Chance served as acting director for a time in 1940 and 1941. He has been a research student at Trinity College, University of Cambridge Faculty of Medicine, England. During the war he served as a staff member of the Massachusetts Institute of Technology's radiation laboratory. At the close of the war he worked and studied at the Nobel Institute in Stockholm on a Guggenheim fellowship. He is a graduate of the University of Pennsylvania and received a degree of Master of Science from there in 1936 and his Ph.D. degree in 1940.

WEST VIRGINIA

Personal.—The following members of the West Virginia State Medical Association were recently elected to honorary lifetime membership. Drs. Carson A. Willis, Clarksburg; Thomas W. Moore, Huntington; W. Byrd Hunter, Huntington; Horace S. Falconer, Fairmont, and Patrick L. Gordon, Charleston.

Atmospheric Pollution in Charleston Area.—A study of soot fall in the metropolitan area of Charleston has been made by the Bureau of Industrial Hygiene of the West Virginia Department of Health. Over a period of two and one-half years samples were collected and measured at twelve stations in 1946 and at six stations in 1947. The study shows that the problem is of sufficient magnitude to warrant serious consideration of plans for an over-all atmospheric pollution control program.

WASHINGTON

New Director of Health.—Dr. John A. Kahl, Seattle, has been appointed acting director of the Washington State Department of Health succeeding Dr. Arthur L. Ringle, who resigned December 3. Dr. Kahl is a graduate of University of Nebraska College of Medicine, Omaha, and has served intermittently as assistant director for several years.

Results of Immunization Program.—The value of immunization programs carried out by private physicians and local health departments of the state was again shown in the year 1948 by declines in smallpox, diphtheria and whooping cough. Since the vaccination of hundreds of thousands of Washingtonians in 1946, smallpox has not been reported in the state, where previously the average was 12 cases yearly for five years. Diphtheria dropped from 186 cases in 1947 to 88 in 1948 and whooping cough dropped from 1,480 in 1947 to 988 in 1948. Typhoid incidence was reduced to 12 cases, the lowest in the state's history. Pasteurization of milk and the fight against Bang's disease in cattle lowered undulant fever cases from 65 in 1947 to 43 in 1948. Diseases for which there is no immunization showed no such declines. Poliomyelitis cases in 1948 were 378 with 168 in 1947; the ten year average is 218 cases. Measles gained 10 times, with 1,249 cases in 1947 and 12,748 in 1948. Mumps cases were 12,164 in 1948, 3,633 in 1947; scarlet fever cases 1,811 in 1948 and 1,450 in 1947.

PUERTO RICO

Survey to Establish Medical School.—A preliminary study on the establishment of a school of medicine in Puerto Rico was conducted in San Juan by Dr. Robert A. Lambert, first medical director of the Puerto Rico School of Tropical Medicine, and government officials. Dr. Lambert conferred with Dr. Juan A. Pons, commissioner of education, Dr. Pablo Morales Otero, present director of the School of Tropical Medicine, Dr. Jose N. Gandara, member of the Superior Council of Education, and Drs. Ramon M. Suarez and Manuel de la Pila Iglesias, the last two members of the commission, who in 1944 made the first survey on the establishment of a school of medicine, under the auspices of the University of Puerto Rico. Drs. Rufus C. Harris, president of Tulane University, and Maxwell E. Lapman, director of the Tulane School of Medicine, were invited to cooperate in the survey now being conducted. The possibilities that a final report will be rendered on this project are more favorable than two years ago. Members of the majority party controlling the legislative branch of the government have expressed their desire to approve the measures necessary to carry on this project. For the establishment of this school of medicine a law appropriating $300,000 was approved by the governor in 1948.

GENERAL

Health Association Meeting.—The Southern Branch of the American Public Health Association will meet at the Baker Hotel, Dallas, Texas, April 14-16 under the presidency of Dr. John M. Whitney, New Orleans. *Section meetings will be held* on Friday afternoon. Among the speakers at the general session is Dr. Rolla E. Dyer, Bethesda, Md.

Results of Study of Child Health Services.—The American Academy of Pediatrics will announce the findings and recommendations resulting from a three year nationwide Study of Child Health Services at a dinner April 2 at the Roosevelt Hotel, New York. The speakers will be Drs. Warren R. Sisson, Boston, president of the academy; Thomas Parran, Pittsburgh; Roscoe L. Sensenich, President, American Medical Association, South Bend, Ind., and Mr. Winthrop Rockefeller, New York.

Conference on Coordinating Congresses of Medical Sciences.—A general constituent assembly to found a permanent *Council for the Coordination of International Congresses* of Medical Sciences will be held in Brussels, Belgium April 4-9. The conference is being sponsored jointly by the United Nations Educational, Scientific and Cultural Organizations and the World Health Organization. More than fifty representatives from international medical organizations and associations will attend.

Thoracic Surgery Meeting.—The American Association for Thoracic Surgery *will hold its annual meeting March 29-31* at the Hotel Roosevelt, New Orleans, under the presidency of Dr. Edward D. Churchill, Boston. Among those invited to present papers are:

Henry K. Beecher, Boston, Anesthesia for Thoracic Surgery, a Study of the Effect of the Open Pleura on the Blood Gases.
Homer L. Skinner, Staten Island, N. Y., *Pneumonectomy Followed by Immediate Thoracoplasty.*
Hawley H. Seiler, Oteen, N. C., Pulmonary Resection of Metastatic Malignancy.

Survey of the Nursing Profession.—The first authoritative survey among U. S. nurses since the war, recently conducted by the American Nurses' Association, reveals that there are today 435,000 registered professional nurses in this country, of whom only 280,500 or 64.5 per cent, are active. Of these, the largest concentration is in the Middle Atlantic states. The survey shows that the number of professional nurses in hospitals and schools of nursing increased 13.4 per cent from 1946-1947; in addition, the number of public health nurses and the number of professional nurses employed by government agencies rose in 1948. Enrolment of student nurses Jan. 1, 1948 totaled 91,643, a drop of about 14 per cent from the 106,900 students enrolled Jan. 1, 1947.

Industrial Medicine Conference.—The spring meeting of the New England Conference of Industrial Physicians and Surgeons will be held April 27 at Yale University School of Medicine, New Haven, under the sponsorship of the Connecticut State Medical Society, State Department of Health and the university. Members of the state medical society and friends are invited to attend. Papers will be presented on "Cardiac and Vascular Diseases, Their Industrial Significance." Out of state speakers will be Dr. Arthur M. Master, New York, on "Coronary Artery Disease, Pathogenesis with Consideration of Relationship of Effort to Myocardial Infarction," and Dr. Hugh Montgomery, Philadelphia, "Obliterative Disease of the Arteries." *The subject of the dinner address at 7 p. m. is* "Education in Industrial Health and Public Health." The registration fee is $3.

Residencies in Industrial Medicine.—General Motors Corporation announces an expansion of its In-Plant Training Program for physicians wishing practical experience in industrial medicine and is prepared to accept ten residents for the year beginning July 1949. Each appointee will receive orientation instruction in General Motors Medical Procedure and Industrial Hygiene Control, followed by assignment to a General Motors plant for a year's resident training. Each plant medical department will be affiliated with a hospital approved for intern and resident training by the Council on Medical Education of the American Medical Association. Each candidate must be a graduate of a Class A medical school, have completed at least a twelve months' rotating internship or its equivalent in hospital training, and have an interest in occupational health. He must also be licensed to practice medicine in the state to which he is assigned. Letters of application should be addressed to the Medical Consultant, General Motors Corporation, 3044 West Grand Boulevard, Detroit 2.

Allergists Annual Meeting.—The annual meeting of the American College of Allergists will be held in Chicago at the Palmer House April 14-17, under the presidency of Dr. George E. Rockwell, Milford, Ohio. Among those invited to present papers are:

Paul Holinger, Chicago,
Abel Froman, Chicago, [illegible] Lungs and Bronchi.
Jerome R. Head, Chica [illegible] Complications of Calcified Hylus Lymph Glands.
Emmet F. Pearson, Springfield, Ill., Studies of Chronic Bronchitis.
Samuel J. Prigal and Moses L. Furman, New York, Use of Bacitracin in Aerosol Form.
Karl D. Figley, Toledo, Ohio, Use of Concentrated Extract in the Treatment of *Mold-Sensitive Patients.*
Edwin R. Levine, Chicago, Effect of Bronchial Spasm on Pulmonary Function.
Harry S. Bernton, Washington, D. C., and Mary Loveless, New York, Cottonseed Protein vs. Cottonseed Oil Sensitivity.
Carl R. Rogers, Ph.D., Chicago, A Philosophy of Professional Relationships with Individuals.
Walter F. Rongaus, Donora, Pa., The Donora Catastrophe.
Tzvee N. Harris, Philadelphia, Antibody Formation in Young Animals.
Benjamin F. Feingold, Los Angeles, Infection in the Allergic Child.
James C. Overall, Nashville, Tenn., Drug Therapy in Hay Fever and Asthma in Children.
W. Ambrose McGee, Richmond, Va., Gastro-Intestinal Allergy in Children.

The informal banquet will be held Saturday evening at 7:30.

Community Health Institute.—The Chamber of Commerce of the United States will present a National Institute on Community Health April 7 at the Netherlands-Plaza Hotel in Cincinnati beginning at 9:30 a. m. "Has Your Community Kept Pace with the Nation's Health Progress?" will be the question under discussion with A. D. Marshall, assistant secretary, General Electric Company, as moderator. Among the speakers will be:

Mr. Earl O. Shreve, Washington, D. C., president, Chamber of Commerce, Opening Remarks.
Dr. George M. Wheatley, New York, Contribution of Governmental Public Health Services.
Dr. James R. Miller, Hartford, Conn., Contribution of the Medical Profession.
Mr. Albert V. Whitehall, Washington, D. C., Contribution of Hospitals.
Mr. O. C. Hubert, Atlanta, Ga., What Atlanta Has Done.
Mr. Herbert Garster, Farrell, Pa., What Farrell Has Done.
Mr. Robert A. Hornby, San Francisco, A Businessman's Appraisal of the Past, Present and Future.

Discussion periods will follow the morning and afternoon programs. At the luncheon Mr. Shreve will speak on "The Employer and His Workers' Health." Believing that more effective community health work is highly desirable, the Chamber of Commerce has planned the institute to stimulate the interest of businessmen and business organizations in their community health problems and to foster intelligent action.

CORRECTION

Systemic Administration of Bacitracin in Surgical Infections.—The first word in the fifth line of the abstract with this title appearing in The Journal, March 12, page 739, should be "systemic" instead of "systematic." The second word in the second line in the right hand column of this same abstract should read "without" instead of "with."

Marriages

Claude Lowry Pressly, Statesville, N. C., to Miss Margaret Amelie Mechlin of Washington, D. C., February 5.

Herbert Clifton Allen Jr., Richmond, Va., to Mrs. Elisabeth Hunt Wheeler of Bedford, Pa., February 1.

Seruch T. Kimble Jr., Washington, D. C., to Miss Helen Louise Matchett of Encino, Calif., January 15.

Richard Albert Martorell, to Miss Rhoda F. Knight, both of Tampa, Fla., in Cairo, Ga., February 5.

John Henry Holden, Staten Island, N. Y., to Miss Janet Scott Jacobs at Portland, Me., January 15.

Leo John Herbert, Syracuse, N. Y., to Miss Elizabeth Sweeney of New York, January 29.

Robert Stanton Sherman Jr., to Dr. Mary Jane Jensen, both of San Francisco, January 27.

Sidney Elian Wanderman, New York, to Miss Jeannette Boskoff of Brooklyn, February 14.

H. Kelvin Magill, Raton, N. M., to Miss Geraldine Sweet of Boston, January 24.

H. Earle Conwell to Mrs. Mary Lou Hill, both of Birmingham, Ala., January 16.

Deaths

Noble Alvin Upchurch, Jacksonville, Fla.; born in Callahan, Fla., May 31, 1877; Vanderbilt University School of Medicine, Nashville, Tenn., 1900; member of the American Medical Association; past president of the Duval County Medical Society; served the American Public Health Association for many years in various offices and was made a fellow of that organization in 1930 in recognition of his outstanding contributions in field of public health; later recognized by the Cuban government when he was chosen the recipient of the Finlay Award and cited for this achievements; past president of the Florida Public Health Association; for eighteen years, from Jan. 18, 1925 to Dec. 31, 1942, health officer of the city of Jacksonville; retired Jan. 1, 1943 because of ill health; member of the staffs of St. Luke's and St. Vincent's hospitals; served as physician to the athletic department of the old Duval High School; medical examiner for many life insurance companies; died December 31, aged 72.

Robert Koritschoner ⊕ Kansas City, Mo., born in Vienna, Austria, May 9, 1884; Medizinische Fakultät der Universität, Wien, Germany, 1910; specialist certified by the American Board of Pathology; member of the American Association of Pathologists and Bacteriologists, College of American Pathologists and the American Society of Clinical Pathologists; director of pathology at the University of Kansas City School of Dentistry; affiliated with the Douglass Hospital, Kansas City, Kan., Wheatley-Provident Hospital and the Menorah Hospital, where he died November 15, aged 64, of carcinoma of the pancreas.

Arthur Thomas Davis, Riverhead, N. Y.; born in Utica, N. Y., Dec. 11, 1882; Albany Medical College, 1904; member of the American Medical Association; for many years commissioner of health of Suffolk County; formerly commissioner of health for Delaware; served during World War I; formerly associated with the U. S. Public Health Service; consulting epidemiologist for the Mather Memorial Hospital in Port Jefferson; epidemiologist for the Southside Hospital in Bayshore; consulting physician to the Southampton (N. Y.) Hospital; died December 17, aged 66, of chronic nephritis with uremia.

Julian Baker Blue ⊕ Memphis, Tenn.; born in 1884; University of Louisville (Ky.) Medical Department, 1907; specialist certified by the American Board of Ophthalmology and of the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; past president of the Shelby County Medical Society; for many years on the faculty of the University of Tennessee College of Medicine; on the staff of the Methodist Hospital, where he died January 25, aged 64.

William Lemuel Alcorn ⊕ Washington, Iowa; Keokuk (Ia.) Medical College, College of Physicians and Surgeons, 1904; past president of the Washington County Medical Society; director of the Washington State Bank; died November 20, aged 68.

Frank Wesley Allin ⊕ Chicago; Rush Medical College, Chicago, 1905; assistant professor of pediatrics (Rush) emeritus, University of Illinois College of Medicine; on the examining board during World War I; served on the staffs of the Garfield Park Community Hospital and the Presbyterian Hospital, where he died December 28, aged 79, of coronary thrombosis.

Joseph S. Ayers, Newark, N. J.; New York Homeopathic Medical College, 1883; died November 15, aged 88, of coronary thrombosis.

De Witt Baer, Steele, N. D.; State University of Iowa College of Medicine, Iowa City, 1908; member of the American Medical Association; died November 20, aged 63, of hypertension.

Andrew E. Bell, Mooresville, N. C.; University of Maryland School of Medicine, Baltimore, 1897; member of the American Medical Association; formerly member and chairman of the school board; affiliated with the Lowrance Hospital; vice president of the First National Bank; died November 24, aged 81, of pyelonephrosis.

Linford Shepherd Besson ⊕ Portland, Ore.; Hahnemann Medical College and Hospital of Philadelphia, 1915; for many years member of the Oregon Board of Medical Examiners, of which he had been a secretary treasurer; served overseas during World War I; affiliated with the Physicians and Surgeons Hospital, where he died December 1, aged 60, of coronary occlusion.

Joseph Henry Blomer, Quincy, Ill.; Rush Medical College, Chicago, 1906; member of the American Medical Association; on the staff of St. Mary's Hospital, where he died December 2, aged 68, of carcinoma of the left lung.

William Ballantine Boyd, East Windham, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1905; for many years on the staff of the Presbyterian Hospital in New York; died in Intercession City, Fla., December 1, aged 71, of cardiac failure and bronchial asthma.

Elmer E. Clark, Oakley, Ill.; Barnes Medical College, St. Louis, 1898; died December 8, aged 78, of injuries received when his automobile was struck by a train.

Edward Clifton Clayton ⊕ Leeds, Ala.; Birmingham Medical College, 1909; died in South Highland Infirmary, Birmingham, November 24, aged 63, of complications following a ruptured appendix.

Robert James Curdy ⊕ Kansas City, Mo.; Washington University School of Medicine, St. Louis, 1895; specialist certified by the American Board of Ophthalmology; member of the American Academy of Ophthalmology and Otolaryngology and the American Ophthalmological Society; fellow of the American College of Surgeons; on the staffs of St. Margaret's Hospital, Kansas City, Kan., and St. Mary's, St. Luke's, Kansas City Municipal and Children's Mercy hospitals; died December 15, aged 80.

Charles Davis, New Holland, Ohio; Eclectic Medical College, Cincinnati, 1892; died in the Grant Hospital, Columbus, November 14, aged 81.

Augusto de Mier Alonso, Lafayette, La.; Louisiana State University School of Medicine, New Orleans, 1942; died November 27, aged 31, as the result of an automobile accident.

William Joseph Doyle, St. Louis; Beaumont Hospital Medical College, St. Louis, 1901, and Washington University School of Medicine, St. Louis, 1903; member of the American Medical Association; fellow of the American College of Surgeons; for many years affiliated with the City hospital; died in St. Vincent's Hospital November 22, aged 75, of carcinoma of the lung.

George Adam Drescher ⊕ Lewiston, Mich.; Detroit College of Medicine, 1915; examining physician for local draft board during World War II; formerly practiced in Detroit, where he was affiliated with Harper and Deaconess hospitals; died December 16, aged 61, of cerebral hemorrhage and diabetes insipidus.

Sidney Weiss Durschlag ⊕ Cleveland; Ohio State University College of Medicine, Columbus, 1931; specialist certified by the American Board of Otolaryngology; flight surgeon and captain in the medical corps of the Army of the United States during World War II; served as an examiner for the Veterans Administration; affiliated with the Polyclinic Hospital and the Mount Sinai Hospital, where he died December 16, aged 42, of cancer of lung.

Jerome Perley Fickett ⊕ Portland, Me.; Medical School of Maine, Portland, 1898; formerly member of the state legislature; served as health officer of Naples; died recently, aged 73, of carcinoma.

Edward J. Fleetwood, Lincoln, Neb.; University of Nebraska College of Medicine, Omaha, 1902; died in Pomona, Calif., recently, aged 76, of arteriosclerosis and hypertension.

Rhoda Galloway-Yolton, Bloomington, Ill.; Woman's Medical College, Chicago, 1887; died in the Brokaw Hospital, Normal, December 23, aged 86, of myocarditis and arteriosclerosis.

William John Gatti, Philadelphia; College of Physicians and Surgeons, Baltimore, 1914; died in the Mercy Hospital recently, aged 56, of bronchopneumonia and arteriosclerotic heart disease.

William Armistead Gills ⊕ Passed Assistant Surgeon, Lieutenant, U. S. Navy, retired, Norfolk, Va.; Medical College of Virginia, Richmond, 1900; entered the navy on Dec. 22, 1920 and retired on Dec. 15, 1923 for incapacity resulting from an incident of service; served during World War I; died November 23, aged 72, of coronary occlusion.

Frederick S. Greenbaum, Los Angeles; Rush Medical College, Chicago, 1902; died November 25, aged 70.

Charles Avery Hansen, Mount Vernon, Wash.; American Medical Missionary College, Battle Creek, Mich., and Chicago, 1906; at one time a missionary; died December 13, aged 76.

Edgar E. Hart, Oklahoma City; St. Louis College of Physicians and Surgeons, 1896; formerly associated with the Indian Service; died in Wesley Hospital recently aged 80, of tumor of the prostate and paralysis.

Paul Headland, Galesburg, Ill.; Loyola University School of Medicine, Chicago, 1919; member of the American Medical Association; served during World War II; in charge of the student health service at Knox College; died January 7, aged 60, of acute coronary occlusion.

Virginia Borum Pope Hickerson, Cincinnati; University of Virginia Department of Medicine, Charlottesville, 1926; certified by the National Board of Medical Examiners; formerly member of the staff of the Mississippi State Tuberculosis Sanatorium in Sanatorium, Miss.; resident physician at Dunham Hospital, where she died December 25, aged 57, of cerebral hemorrhage.

Milton M. Kay, Encinitas, Calif.; Northwestern University Medical School, Chicago, 1905; member of the American Medical Association; died in Paradise Valley Sanitarium and Hospital in National City, November 16, aged 76, of sprue.

Jay S. Liebman, Alexandria, Va.; Atlanta College of Physicians and Surgeons, 1910; died in Martinsburg, W. Va., November 20, aged 64.

Raffaele Lorini, Beaumont, Calif.; University of Pennsylvania Department of Medicine, Philadelphia, 1881; member of the American Medical Association; formerly health officer of Coronado; died November 7, aged 89.

George Malcolm MacGregor, Kent, Wash.; Johns Hopkins University School of Medicine, Baltimore, 1902; member of the American Medical Association; formerly health officer; served on the staff of the Auburn (Wash.) General Hospital; died in Steilacoom November 11, aged 77, of arteriosclerotic heart disease.

Robert F. McLean, Gibbon, Neb.; Western University Faculty of Medicine, London, Ontario, Canada, 1906; served on the staff of the Good Samaritan Hospital in Kearney, died November 25, aged 65, of lung tumor.

Frank Rouse Morley, Sedalia, Mo.; University Medical College of Kansas City, 1901; member of the American Medical Association; died November 25, aged 70, of coronary thrombosis.

Joseph Sweetman Parent ⊕ Galway, N. Y.; Albany (N. Y.) Medical College, 1886; served as health officer in the town and village of Galway; died December 7, aged 87.

Napoleon B. Rundall, Petaluma, Calif. (licensed in California in 1918); for many years city health officer; died December 16, aged 66.

Jibran Yusuf Skeirik ⊕ Lawrence, Mass.; Harvard Medical School, Boston, 1929; certified by the National Board of Medical Examiners; member of the New England Obstetrical and Gynecological Society; died in the Beth Israel Hospital, Boston, December 5, aged 55.

Colbert Cecil Stepp, Hatfield, Ky.; Kentucky University Medical Department, Louisville, 1906; died in Williamson, W. Va., December 18, aged 76.

James Lona Salmon Stewart ⊕ Boise, Idaho; Rush Medical College, Chicago, 1899; member of the founders group of the American Board of Surgery; member of the American Association for the Surgery of Trauma; fellow of the American College of Surgeons; served during World War I; affiliated with St. Alphonsus and St. Luke's hospitals; died December 15, aged 73.

Edward Charles Straessley ⊕ Beaver Falls, Pa.; University of Maryland School of Medicine, Baltimore, 1912; died in the Providence Hospital December 7, aged 59, of coronary artery disease.

James D. Stuart, Crystal, Mich.; Baltimore University School of Medicine, 1899; for many years coroner of Genesee County; died December 8, aged 74.

Walter Thomas Swink, Memphis, Tenn.; College of Physicians and Surgeons of Chicago, 1896; Vanderbilt University School of Medicine, Nashville, 1900; formerly associate professor of medicine at the University of Tennessee College of Medicine; member of the American Medical Association; served during World War I; affiliated with John Gaston Hospital; died December 20, aged 78, of pneumonia.

Andrew John Taddeo, New York; University and Bellevue Hospital Medical College, New York, 1929; served during World War II; on the staff of the Morrisania Hospital; died December 24, aged 49.

Ernest Taylor Tappey, Grosse Pointe Farms, Mich.; College of Physicians and Surgeons, medical department of Columbia College, New York, 1879; formerly on the faculty of Wayne University College of Medicine; died December 22, aged 95, of left lobar pneumonia.

Frank Donaldson Thomas ⊕ St. Petersburg, Fla.; Hahnemann Medical College and Hospital of Philadelphia, 1912; member of the Medical Society of the State of Pennsylvania; served during World War I; formerly on the staffs of the Nesbit Memorial Hospital in Kingston, Pa., and the Homeopathic Hospital in Wilkes-Barre, Pa.; affiliated with the Veterans Administration; died January 8, aged 59.

Frank Mathias Tombaugh ⊕ Burlington, Iowa; Northwestern University Medical School, Chicago, 1896; past president of the Iowa State Surgical Society and the Des Moines County Medical Society; fellow of the American College of Surgeons; medical examiner for local draft boards during World Wars I and II; affiliated with the Mercy Hospital; died December 29, aged 79, of cerebral hemorrhage.

Aaron Samuel Torrens ⊕ Hanford, Calif.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1909; formerly city and county health officer; medical examiner for the draft board during World Wars I and II; died January 2, aged 69, of myocardial failure.

Victor Floyd Tremor, Indianapolis; Indiana University School of Medicine, Indianapolis, 1923; member of the American Medical Association; served during World Wars I and II; formerly affiliated with the Veterans Administration Hospital, where he died December 31, aged 53, of myocardial infarction.

Granville B. Trout, Zanesville, Ohio; Starling Medical College, Columbus, 1892; past president of the Muskingum County Academy of Medicine; formerly county coroner; affiliated with the Bethesda Hospital; medical examiner for the Metropolitan Life Insurance Company; died in the Good Samaritan Hospital, December 15, aged 87, of complications as the result of a fractured hip received in a fall.

Benjamin Randall Tupper, Schenectady, N. Y.; College of Physicians and Surgeons, medical department of Columbia College, New York, 1888; affiliated with the New York Post Graduate Hospital in New York; died in the Ellis Hospital December 8, aged 86, of coronary occlusion.

George Hampden Upton, New Orleans; Tulane University of Louisiana School of Medicine, New Orleans, 1907; member of the American Medical Association; affiliated with Mercy Hospital; died January 29, aged 66, of thrombosis.

Samuel Burns Van Dalsem, San Jose, Calif.; Hahnemann Medical College and Hospital of Philadelphia, 1902; member of the American Medical Association; served during World War I; died January 18, aged 73, of carcinoma.

James Murray Washburn, Lake Lure, N. C.; Northwestern University Medical School, Chicago, 1899; fellow of the American College of Physicians; formerly practiced in Chicago, where he was associate professor of medicine, emeritus, at his alma mater and on the staff of Passavant Memorial Hospital; at one time associated with the U. S. Public Health Service; mayor for many years; died January 16, aged 75, of carcinoma.

Cyril Aloysius Whalen ⊕ Mahanoy City, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1934; past president of the board of education; died in the Locust Mountain Hospital, Shenandoah, January 25, aged 40, of Hodgkin's disease.

Leander C. White ⊕ Adair, Okla.; Kentucky University Medical Department, Louisville, 1905; past president and secretary of the Mayes County Medical Society; local surgeon for the Missouri, Kansas and Texas Railroad; examiner for Mayes County Selective Service during World Wars I and II; elected first coroner of the Mayes County in 1907; served on the school board; died December 4, aged 75, of heart disease.

John Wyman Whiteside, Chicago; Rush Medical College, Chicago, 1884; died January 16, aged 91, of myocarditis.

Clayton Lester Wood, Washington, D. C.; Medical College of Virginia, Richmond, 1918; served during World War I; medical director of the Disabled American Veterans; for many years affiliated with the Veterans Administration; died January 3, aged 60.

Swan G. Wright, Minneapolis; Minneapolis College of Physicians and Surgeons, 1908; member of the American Medical Association; served on the staff of the Swedish Hospital, where he died December 13, aged 69, of heart disease.

The National Association for the Prevention of Tuberculosis

The National Association for the Prevention of Tuberculosis has celebrated its jubilee. Its recommendations for the education of the public, the purity of our milk supply and the erection of sanatoriums gradually became parts of a national scheme of tuberculosis control, and great saving of life and prevention of the disease followed. In 1898, with a population of 36,000,000, there were 70,000 deaths from tuberculosis in England and Scotland. In 1948, with a population of 48,000,000, the deaths are expected to be under 27,000. The association has played an important part in the campaign for mass radiography. In the last few years increased attention has been given to the problem of tuberculosis in the British Empire, particularly in the smaller colonies, where it is a serious menace, and with the disease within measurable distance of control at home this may well be the field of future work. The association has already carried out research surveys in the West Indies, the Gold Coast and elsewhere. It also offers colonial scholarships for study in this country. The six scholars for 1948 came from East Africa, the Gold Coast, Malta, Singapore, the Sudan and Trinidad.

Extended Safeguards for Workmen

An employers' liability bill entitled Safety of Employment has been introduced in the House of Commons. It greatly extends the liability of employers. It proposes to protect all who work under a contract of employment and brings within its scope such employees as agricultural workers, local government employees, domestic servants and merchant seamen. At present an injured workman can claim benefit under the National Insurance (Industrial Injuries) Act, and in some cases he can in addition claim damages at common law, if he can prove that the employer was negligent. The object of the bill is to improve working conditions and to minimize claims for damages by establishing a minimum standard of safety. It obliges the employer to take all practicable steps to prevent injury at work, including injury to health, and lays down that it shall not be taken as fulfilment of his obligation for him to have followed customary practices. Further provisions empower the Minister of Labor to prescribe minimum standards of safety in a particular occupation. The bill is in line with much recent legislation, which has aimed at serving the interests of the workman in every possible way.

Medical Students to Act as Nurses

An important innovation in the training of students has taken place at the London Hospital. They are to be trained in nursing, which means tidying beds, washing patients and making tea in male wards. Dr. Clark-Kennedy, dean of the hospital, thus explains the innovation in the *Daily Mail:* "When a medical student becomes a doctor it is part of his duty to supervise nursing. He must teach mothers, daughters, sisters and wives how to nurse patients at home. How can a student know if nursing is being well done if he has not had some training himself?" The students will be still under the control of the dean and not under that of the matron, but the dean has delegated his authority to the ward sisters, who will direct the students' activities and teach them the principles of good nursing.

March 1, 1949.

Deadlock on National Medical Service

The Government is proposing desperate measures to overcome the resistance of the British Medical Association to so-called free medicine and the National Health Service plan.

The Government proposes to launch an intensive publicity campaign advising people to pay only half any account from their doctor; it will protect a patient against legal action for recovery of the other half, and will advise doctors that they can collect it by applying to the Government under the Medical Benefits Act.

This would not be a breach of the Constitution forbidding civil conscription of doctors or of the promise that no compulsion would be used to get doctors into either the free medicine or national health scheme, considers the Government.

The Government may issue new regulations involving prosecutions and heavy penalties for doctors writing prescriptions which appear in the free medicine formulary without using the official free medicine form.

The Minister for Health, Senator McKenna, was advised that doctors had used the same prescription as that in the Government formulary, but had added a different flavoring to avoid exact conformity. This is difficult to understand, because nearly all doctors refused to accept the formularly and forms when delivery was attempted.

The attitude of the British Medical Association is that they have never opposed the Government policy to give the people "free" medicine and "half-free" medical treatment.

The British Medical Association is anxious to offer full cooperation in such services, provided only that there shall not be interference with the liberty of doctor or patient, or with the intimate and confidential relationship between them.

The Government ignored the objections of the British Medical Association. Thus in relation to "free" medicine, only those medicines in a Government list are "free" and then only if the doctor writes his prescription on a Government form, the use of which automatically places him under the control of regulations and within the scope of penalties, both of which can be varied at the behest of the Government or the Minister.

Again, in the National Health Service Act, the Government aims to compile a schedule of the fees payable for attendance by general practitioners in accordance with which the patient will pay half and the Government half, but only if the doctor agrees to be bound by changeable regulations which require disclosure of details of the patient's illness, which are able to limit the type of practice he may undertake and which alter the amount and manner of payment for his services as the Government wills.

To such conditions the profession can never submit, nor will the Government countenance their removal. "Who then is denying the people these great social benefits?" asks the British Medical Association. Doctors cannot give them without the sacrifice of their freedom, but the Government can, at the expense only of the sacrifice of their lust for power. Let the Government decree that all medicines, or certain expensive single drugs, prescribed on a doctor's private form, shall be free; let it determine also that it will refund to the patient half his medical fees on production of a receipt.

The reported proposal of the Government to exercise coercion by prosecution and fines on doctors whose offense stemmed only from the value they placed on their freedom deserved only contempt.

The profession will rely not only on learned legal opinion that the Government possesses no legal or constitutional power to effect this iniquity, but also on the will of the great Australian nation to see justice and fair play.

The British Medical Association is holding fast to a fundamental ethical principle of the medical profession—that a doctor's first duty is to his patient and that duty cannot be subordinated to any Government direction. Threats of fines and other forms of intimidation certainly will not win the cooperation of the medical profession.

When the Federal Government obtained from the people of Australia by referendum in 1946 constitutional authority to legislate for national medical and dental services, the new Commonwealth power was limited by a proviso excluding any form of civil conscription. Should the Chifley Government deliberately provoke a legal contest with the medical profession over this constitutional safeguard, there can be no beginning of any sort of national health service until it is settled. There is also the much bigger political question, whether the national health service projected by the Government will, under Australian conditions and under a socialist administration, give the people real benefits commensurate with what they will have to pay for it.

Nothing offered by the Government, neither "free" medicine nor part payment of doctors bills, is really going to be a gift to any one. It will have to be paid for by heavy taxation. The British scheme is already costing 52,000,000 pounds a year more than was estimated, and the New Zealand Government has had to review the cost of its scheme.

On Dec. 22, 1948, the Government, through Senator McKenna, advised the British Medical Association that every endeavor had been made by the Government to secure the cooperation of the association, which was grievously lacking in a sense of social responsibility. The Government does not intend that its proposals should be further delayed or frustrated by the British Medical Association. The Government has decided that, within the limits of its constitutional power, it will proceed to put its plans into operation. One of the most valuable assets of the British Medical Association is the support of the Australian public and press. There has been surprisingly little public demand for the "benefits" of "free" medicine. Even in poorer and industrial areas where they expected patients might exert some pressure, the people are apathetic.

Although there have been some break-aways throughout the campaign, most druggists have supported the scheme because the Government endorsed certain principles laid down by the Federated Pharmaceutical Guild. Druggists claim that they have entered into a purely business contract with the Federal Government, and were not prepared to take sides into a dispute between the British Medical Association and the Government.

In practically every doctor's rooms is a disapproval notice setting out the reasons for nonparticipation in the scheme. Scarcely any of them have the prescription forms in their possession.

Politicians in Canberra are becoming increasingly worried about the public reaction to the recent Government attempts to force doctors to participate in their plans. The effect of this public feeling may be noticed in the national elections in May. The British Medical Association may go to the High Court to test the validity of the Pharmaceutical Benefits Act and the National Health Services Act. The Government has already on its hands a long legal battle over the nationalization of banks, and it would not be disposed to engage in another.

The federal council of the British Medical Association will hold a four day meeting in Melbourne from March 1. Counter measures to combat the Government's latest offensive will be discussed.

Vital Statistics, 1947

One of the lowest infant mortality rates in the world and an increased birth rate are features of the vital statistics for Australia for 1947.

The infant mortality rate is 28.52 per thousand live births. This can be compared with 41 for Britain, 45 for Canada, 35 for South Africa, 32 for the United States and 25 for New Zealand (excluding the Maori population).

The birth rate for 1947 was 24.1 per thousand population, an increase of 0.5 per thousand over the previous year. In Britain it was 20.7, Canada 28.6, New Zealand 26.4, South Africa 27.2 and United States 25.9.

The death rate was 14.4 per thousand population, an increase of 0.8 per thousand due to a higher rate in the older age groups.

Metric System of Prescribing

Only a small minority of the doctors in Australia write their prescriptions in the metric system. There is no argument against the metric system; every one is agreed, in principle, that it is the right thing to do. But the convenience of the half fluid ounce filling a tablespoon and the traditional background of the British system are rather too strong for the idealism inherent in the metric system.

The newer drugs, especially those in tablet form, are being prescribed in grams, but the "bottle" is 4.6 or 8 ounces, with the prescription written to suit.

As to Latin, it will be generally conceded that English is easier for practical purposes and that few practitioners could write a prescription in grammatical unabbreviated Latin, if they wished. Yet the Latin drug names (with their case endings conveniently chopped off) have become a matter of habit and the abbreviated Latin terms covering standard directions are convenient and probably less ambiguous than abbreviated English would be.

The Australian doctor still likes his quaint symbols and the mysterious phrase which is quite intelligible to those who need to understand it. He still likes his invocation to Jove (or is it Jupiter?). The only occasional tragedy is when a prescription for paraldehyde per rectum is written so badly that the symbol for drachms is mistaken for fluid ounces.

Q Fever Discovery

The report that Q fever had been recognized in Britain adds another country to the number of those in which the disease, originally discovered in Australia, has been found. The United States, Italy, Germany, Switzerland, Morocco, Iraq, Panama and Turkey have already reported the disease among their populations.

Dr. E. A. Derrick, now deputy director of the Queensland Institute of Medical Research in Brisbane, who was the codiscoverer of the Q fever with Professor F. M. Burnet of Melbourne, thought in 1935 that the disease was a purely local curiosity. Some of the general practitioners in Brisbane suburbs having large abattoirs in the district noticed a new type of sickness amongst meat workers. The disease was investigated, and a virus research worker in Melbourne to whom the material from the patients was sent now has the Rickettsia burneti named after him, as it was an infection never previously described. At the same time that it was investigated here the infection was found in Montana (United States) in guinea pigs on which ticks had been fed. But it had not been reported there among human beings.

Q fever is extremely infectious and dangerous to handle in a laboratory. Wherever it is discovered, outbreaks occur among those working on it. In Queensland there have been 3 deaths in the 300 cases reported so far.

The Mental Hospitals in Australia

A steady increase in overcrowding and repeated failure to make any worth while improvement in hospital accommodation are the sorry features of the mental hospitals in Australia.

At some hospitals the nursing and other female staff have been reduced to half. One result of this shortage is that shock therapy has had to be abandoned in some cases because of the demands of routine work on the depleted nursing staff. In some of the mental hospitals of New South Wales the number of patients sleeping in wards is half as many again as the wards were intended to accommodate.

Many institutions are maintained at their present level only because of the devoted and faithful service of the senior nurses, who are working to the limit of their physical capacity.

Florence, Feb. 3, 1949.

First Congress on Antibiotics

The Center for Information and Studies on Antibiotics has organized its first national congress, which was held in Milan under the chairmanship of Professor Redaelli. Professor Pratesi, director, Institute for Chemical Pharmaceutics, University of Pavia, reported on "Studies of Antibiotics from the Chemical Point of View." The speaker recalled that many antibiotic substances are well known, and others are waiting to be isolated, exactly identified and utilized. To date about sixty characteristic substances isolated from germs and from fungi present an antibacterial activity, and about thirty of them have been studied from the point of their clinical action. Attempts to classify them encounter difficulties because of the variety of their nature and mode of action. The speaker suggested a scheme of arranging the antibiotics according to their chemical nature in eight groups as follows: (1) quinones of isocyclic series, (2) phenols, (3) derivatives of pyrazine and of phenazine, (4) unsaturated lactones, (5) derivatives of thiazole (penicillin), (6) streptomycin, (7) polypeptides and (8) enzymes.

The speaker discussed particularly the chemical structure of the various substances, exposing the characteristic groups of each of them and discussing all the possible concepts concerning the mode of action of each group. He finally spoke about the chief antibiotics whose structure has not yet been defined, and among them is streptomycin.

The second subject reported on was "Association of Chemotherapy and Antibiotics in Treatment Directed Against Infection." The speakers were Professor Magrassi from the medical clinic of the University of Sassari and Professor Scalfi, assistant at this clinic. The results of research suggest the importance of the possibility of combining two or several antibacterial compounds in order to obtain a greater efficacy against bacteria. It has been demonstrated that sulfathiazole, the pyridine compounds and sulfadiazine may be combined with the antibiotics for an effect on gram-negative bacteria. Combined administration of penicillin and arsphenamine, and of streptomycin with sulfonamide compounds and penicillin, is of the greatest practical interest. But the most noteworthy results of research are those on the association of streptomycin with sulfones in the treatment of experimental tuberculous infection; these results constituted the starting point for a series of clinical applications, which already have yielded promising results.

The speakers discussed the mechanism through which the great efficacy of some of the associations between chemotherapeutic agents and antibiotics may be realized.

The experimental data are favorable to the employment of the combined treatment with chemotherapeutic agents and antibiotics; particularly convincing were the data obtained with the treatment of experimental infections. Therefore clinical control was undertaken. Many observations were collected during the last years. There is not a single field of infectious pathology in which therapeutic trials have not been carried out, but there remain many points which need clarification. However, some general conclusions may be drawn which confirm the progress made by the experimental studies. Clinical observations have made evident that the association of the chemotherapeutic agents and of the antibiotic provides for an increased antibacterial activity in many but not in all of the infections in man. Such an increased therapeutic efficacy is revealed, for instance, by the association of penicillin with the sulfonamide compounds in the treatment of pneumonia and pneumococcic meningitis and by the association of streptomycin, penicillin and sulfonamide compounds in the meningitis caused by hemophils. An even better evaluation of the therapeutic use of the association of chemotherapeutic agents and of antibiotics has been afforded by the results in the treatment of infections in which the isolated administration of the antibacterial drugs failed. This applies to the various types of association of streptomycin, penicillin and sulfonamide compounds in the infections caused by Eberth's bacillus and by Brucella; the association of streptomycin with sulfadiazine determined a decisive progress in the treatment of brucellosis.

Prof. Pietro Fornara, head of the pediatric department of the main hospital of Novara, reported on the third subject, "The Antibiotics in the Treatment of Meningitis in Infants." According to some statistics, in meningococcic meningitis cure was obtained with sulfonamide treatment in 100 per cent of cases, and the sulfonamide compounds still constitute the basic method of treatment. In cases which are resistant to some of the sulfonamide compounds one may vary the sulfonamide compounds (sulfadiazine, not methylated sulfadiazine, is the most active one), and they may be combined occasionally with antibiotics. The results obtained so far with penicillin are not too brilliant.

Pneumococcic meningitis is difficult to cure. Before the sulfonamide era, the mortality rate was 100 per cent; with sulfonamide treatment it was reduced to 65 to 70 per cent. Even with combined chemotherapeutic treatment the mortality rate remains high. Today the treatment of choice for meningitis caused by Hemophilus influenzae is streptomycin combined with sulfonamide compounds, while in some cases it may be supported by Alexander's serum or penicillin. The association of penicillin with sulfonamide compounds or other chemotherapeutic agents has proved useful in meningitis caused by Streptococcus and in that caused by Staphylococcus (a particularly fatal type).

Reports on results obtained in tuberculous meningitis are scarce and doubtful: Nobody has been able to report a definite cure. The employment of streptomycin is still in the experimental stage. It should be used, but five more years must pass before definite results may be pronounced. In addition to dosage, there is the problem of individual resistance and of allergy. Occasionally, streptomycin should be combined with a sulfone or a vitamin, or with morrhuates or other substances. The speaker obtained the best results with combined treatment with streptomycin and vaccine by mouth.

Before the adjournment of the congress, Professor Frankl (Hungary) reported on his research carried out in collaboration with Professor Melczer concerning a method for prolonging and reinforcing the effect of penicillin. The authors used a 10 to 15 per cent aqueous solution of gelatin which may be administered by intramuscular, intravenous or intraspinal route. Using a single dose of 50 to 200,000 units of penicillin contained in the solution just mentioned, the bacteriostatic concentration of the antibiotic in the blood lasted for eight to ten hours; with an intravenous injection its duration varied from six to ten hours. By intraspinal route 10 to 20,000 units of penicillin in 1 cc. of gelatin furnished a bacteriostatic effect for twenty-four to seventy-two hours. A 25 to 30 per cent solution of gelatin may serve as a vehicle for injections into sinuses. The speakers recommended the use of the preparation in all septic conditions.

The British Medical Association is holding fast to a fundamental ethical principle of the medical profession—that a doctor's first duty is to his patient and that duty cannot be subordinated to any Government direction. Threats of fines and other forms of intimidation certainly will not win the cooperation of the medical profession.

When the Federal Government obtained from the people of Australia by referendum in 1946 constitutional authority to legislate for national medical and dental services, the new Commonwealth power was limited by a proviso excluding any form of civil conscription. Should the Chifley Government deliberately provoke a legal contest with the medical profession over this constitutional safeguard, there can be no beginning of any sort of national health service until it is settled. There is also the much bigger political question, whether the national health service projected by the Government will, under Australian conditions and under a socialist administration, give the people real benefits commensurate with what they will have to pay for it.

Nothing offered by the Government, neither "free" medicine nor part payment of doctors bills, is really going to be a gift to any one. It will have to be paid for by heavy taxation. To date about sixty characteristic substances isolated from germs and from fungi present an antibacterial activity, and about thirty of them have been studied from the point of their clinical action. Attempts to classify them encounter difficulties because of the variety of their nature and mode of action. The speaker suggested a scheme of arranging the antibiotics according to their chemical nature in eight groups as follows: (1) quinones of isocyclic series, (2) phenols, (3) derivatives of pyrazine and of phenazine, (4) unsaturated lactones, (5) derivatives of thiazole (penicillin), (6) streptomycin, (7) polypeptides and (8) enzymes.

The speaker discussed particularly the chemical structure of the various substances, exposing the characteristic groups of each of them and discussing all the possible concepts concerning the mode of action of each group. He finally spoke about the chief antibiotics whose structure has not yet been defined, and among them is streptomycin.

The second subject reported on was "Association of Chemotherapy and Antibiotics in Treatment Directed Against Infection." The speakers were Professor Magrassi from the medical clinic of the University of Sassari and Professor Scalfi, assistant at this clinic. The results of research suggest the importance of the possibility of combining two or several antibacterial compounds in order to obtain a greater efficacy against bacteria. It has been demonstrated that sulfathiazole, the pyridine compounds and sulfadiazine may be combined with the antibiotics for an effect on gram-negative bacteria. Combined administration of penicillin and arsphenamine, and of streptomycin with sulfonamide compounds and penicillin, is of the greatest practical interest. But the most noteworthy results of research are those on the association of streptomycin with sulfones in the treatment of experimental tuberculous infection; these results constituted the starting point for a series of clinical applications, which already have yielded promising results.

The speakers discussed the mechanism through which the great efficacy of some of the associations between chemotherapeutic agents and antibiotics may be realized.

The experimental data are favorable to the employment of the combined treatment with chemotherapeutic agents and antibiotics; particularly convincing were the data obtained with the treatment of experimental infections. Therefore clinical control was undertaken. Many observations were collected during the last years. There is not a single field of infectious pathology in which therapeutic trials have not been carried out, but there remain many points which need clarification. However, some general conclusions may be drawn which confirm the progress made by the experimental studies. Clinical observations have made evident that the association of the chemotherapeutic agents and of the antibiotic provides for an increased antibacterial activity in many but not in all of the infections in man. Such an increased therapeutic efficacy is revealed, for instance, by the association of penicillin with the sulfonamide compounds in the treatment of pneumonia and pneumococcic meningitis and by the association of streptomycin, penicillin and sulfonamide compounds in the meningitis caused by hemophils. An even better evaluation of the therapeutic use of the association of chemotherapeutic agents and of antibiotics has been afforded by the results in the treatment of infections in which the isolated administration of the antibacterial drugs failed. This applies to the various types of association of streptomycin, penicillin and sulfonamide compounds in the infections caused by Eberth's bacillus and by Brucella; the association of streptomycin with sulfadiazine determined a decisive progress in the treatment of brucellosis.

Prof. Pietro Fornara, head of the pediatric department of the main hospital of Novara, reported on the third subject, "The Antibiotics in the Treatment of Meningitis in Infants." According to some statistics, in meningococcic meningitis cure was obtained with sulfonamide treatment in 100 per cent of cases, and the sulfonamide compounds still constitute the basic method of treatment. In cases which are resistant to some of the sulfonamide compounds one may vary the sulfonamide compounds (sulfadiazine, not methylated sulfadiazine, is the most active one), and they may be combined occasionally with antibiotics. The results obtained so far with penicillin are not too brilliant.

Pneumococcic meningitis is difficult to cure. Before the sulfonamide era, the mortality rate was 100 per cent; with sulfonamide treatment it was reduced to 65 to 70 per cent. Even with combined chemotherapeutic treatment the mortality rate remains high. Today the treatment of choice for meningitis caused by Hemophilus influenzae is streptomycin combined with sulfonamide compounds, while in some cases it may be supported by Alexander's serum or penicillin. The association of penicillin with sulfonamide compounds or other chemotherapeutic agents has proved useful in meningitis caused by Streptococcus and in that caused by Staphylococcus (a particularly fatal type).

Reports on results obtained in tuberculous meningitis are scarce and doubtful: Nobody has been able to report a definite cure. The employment of streptomycin is still in the experimental stage. It should be used, but five more years must pass before definite results may be pronounced. In addition to dosage, there is the problem of individual resistance and of allergy. Occasionally, streptomycin should be combined with a sulfone or a vitamin, or with morrhuates or other substances. The speaker obtained the best results with combined treatment with streptomycin and vaccine by mouth.

Before the adjournment of the congress, Professor Frankl (Hungary) reported on his research carried out in collaboration with Professor Melczer concerning a method for prolonging and reinforcing the effect of penicillin. The authors used a 10 to 15 per cent aqueous solution of gelatin which may be administered by intramuscular, intravenous or intraspinal route. Using a single dose of 50 to 200,000 units of penicillin contained in the solution just mentioned, the bacteriostatic concentration of the antibiotic in the blood lasted for eight to ten hours; with an intravenous injection its duration varied from six to ten hours. By intraspinal route 10 to 20,000 units of penicillin in 1 cc. of gelatin furnished a bacteriostatic effect for twenty-four to seventy-two hours. A 25 to 30 per cent solution of gelatin may serve as a vehicle for injections into sinuses. The speakers recommended the use of the preparation in all septic conditions.

Correspondence

TUBERCULOSIS IN RECENT IMMIGRANTS

To the Editor:—In Queries and Minor Notes, January 29, Dr. William A. Evans of Detroit states:

> "I have seen an impressive number of recent immigrants with far advanced active pulmonary tuberculosis. What is being done at the moment?"

Among some of the statements made answering this query are the following:

> "Roentgenograms were made abroad wherever the Public Health Service had medical officers assigned to the consulates and x-ray facilities were available. In the course of medical examinations of visa applicants abroad, those found to have contagious tuberculosis were given class A notifications and visas were refused. . . .
>
> "A provision became effective on Sept. 1, 1948, whereby every applicant for immigration visas will have a roentgen inspection of the chest for tuberculosis and a blood test for syphilis. Those found to have either are rejected. . . . When examinations are conducted at American consulates which lack x-ray and laboratory facilities the applicant may be required to furnish a roentgenogram of the chest with a reading and a blood serologic report. . . . Temporary visitors to the United States are excluded from this requirement but may be subjected to appropriate examination when tuberculosis or syphilis is suspected."

This is a most interesting comment. Is there any reason why temporary visitors to the United States might not have tuberculosis or syphilis? And how does one suspect tuberculosis or syphilis in a fully clothed person who has not been given an examination? And what was done before Sept. 1, 1948?

Let me enumerate some facts which may throw light on this situation. I was the first medical officer of the United States Public Health Service to be attached to the consulate in Berlin, Germany, after the end of the war, being one of four such officers sent to Germany in early 1946 for the purpose of implementing President Truman's program to admit displaced persons to America. By chance, I was the only one of the four officers who had had any formal training in tuberculosis control. We were given a stethoscope, some eye charts, a case of tongue depressors and a blood pressure cuff and told to get going. In fairness to the United States Public Health Service it must be mentioned that we did not take orders from them, being "loaned" as medical advisors to the State Department. It should also be mentioned that by no means did the State Department have to comply with our suggestions. In fact, I am sure that they didn't very often and have since wondered whether it would not have been better for the American taxpayers if we all had stayed home. Consular officers in charge soon made it known that it was quantity and not quality they were interested in. No doubt somebody back in Washington was demanding action from them. They were not the least interested in making arrangements for roentgenograms or laboratory work to exclude contagious disease; they were admittedly only interested in numbers and quotas. The other three officers mentioned were sent to Stuttgart, Frankfurt and Munich. How many cases slipped by their stethoscopes through no fault of their own, we will never know. They felt just as much concern over this as did I.

As regards Berlin, every one knew that tuberculosis was rampant there and, while most of the aliens seeking visas at the consulate were previously examined by physicians of their own choice in Berlin, or by UNRRA physicians on duty in the displaced persons' camps, it was mandatory that they be examined by an authorized physician detailed to the U. S. Consulate before their final papers could be issued for travel to the United States.

The importance of this measure was soon apparent, for, without exception, all applicants for visas presented me with medical certificates attesting to their being free from disease or defects which would prevent them from earning a living. On examining them myself, the disparity between the results of my examination and that done by their own physician was astonishing. It seemed incredible that by inspection alone one could miss such defects as blindness, bilateral cataracts, missing legs and arms, huge hernias, depressed skull fractures, paralyses of extremities and the face, and mental defects. One gained the impression that the bulk of "physicians" practicing in Berlin at that time would sign any statement for a consideration. There is absolutely no reason to think this condition has changed today. I have every reason to believe that many of these so-called doctors never saw the inside of a medical school. They are reaping a harvest while thousands of competent and qualified German physicians are banned from practicing their profession because they are not yet de-Nazified, having held an honorary rank in the S.S. or S.A. Such rank was mostly commensurate with professional achievement rather than their political views. You might say it corresponded to our American College of Surgeons. All professional persons were in the same boat, whether they were school teachers, college professors, engineers, lawyers or physicians. Today, as then, a pack of cigarets or a half pound of coffee would secure from "lung specialists" an affidavit stating "no disease is present." They can probably furnish a roentgenogram of a healthy chest, too, for a small fee! Before one condemns Berlin physicians too much, it must be stated that over 40 per cent of these "diagnostic errors" which I discovered were made by UNRRA physicians, many of whom were graduates of foreign medical schools and could hardly speak English. This should be comforting to the American taxpayers, since they were all commissioned officers. This does not mean, nor am I saying, that there were not competent physicians connected with UNRRA. I am merely reporting what I saw with my own eyes in Berlin.

I took it on myself to put into operation a complete laboratory screening program in the face of tremendous opposition and personal difficulty, not the least of which was lack of both understanding and support; opposition came as well from bureaucrats interested only in quota numbers.

Where to find x-ray apparatus for the job? The Army hospital in Berlin was neither equipped, authorized nor too enthusiastic about giving roentgen examinations and doing blood tests and urinalyses on these displaced persons, since it would overtax their facilities to the breaking point. The UNRRA camp had an excellent German army 35 mm. Siemens-Reineger photofluorographic unit available and no qualified physician to read the films. They, however, would not loan it to the consulate; yet we had to screen these very same persons seeking visas to America. The Russian Army on entering Berlin had ransacked all the hospitals with the result that all existing x-ray equipment was destroyed, carried off or thrown out in the street to rust.

A most cooperative officer, Lieutenant Colonel Ray Connor of the United States Army, Public Health Branch, not only personally took me around to several German hospitals where we "borrowed" some office equipment, but directed me to Professor Horst Boenig, noted pathologist, author of several textbooks on embryology and former professor at the University of Berlin. Professor Boenig was at that time curator of Oskar-Helene Heim, a famous orthopedic hospital. Boenig had many difficulties with the Nazis during the war chiefly because he was a staunch Catholic, and, in addition, was directly responsible for keeping many young Jewish medical students from being expelled from school, much to the displeasure of certain Nazi bigwigs. Boenig, who could not speak one word of English, put his patched-up, broken-down, ancient x-ray apparatus at my disposal, provided that I could procure the necessary film and chemicals for developing, since the little he had at his disposal was badly needed by inmates of the hospital. This alone was an operation of no small magnitude, since all materials had to be procured from German sources, and in all cases by barter arrangement. Neither the State Department nor any other department was interested in this matter, and so I was entirely on my own.

This x-ray apparatus, being one of few operating in Berlin, was in operation almost eighteen hours daily. Since electric power was rationed (which meant the current might be shut off from four to eight hours daily), it was necessary to crowd much work into the hours when the current was available. The fact that one was never sure when the current would be shut off did not help matters. Long lines of ill and injured German civilians on carts, stretchers and crutches were drawn up in the dark, cold, damp, tomblike halls of the bombed-out and fire-gutted hospital, awaiting their turn for roentgen examination. The hospital owned no spare x-ray tube, and, if the one in operation ever blew out, its loss would have been a major catastrophe to the hospital and to the x-ray screening program which I had set up with my own judgment and without official sanction. I had to even purchase x-ray view boxes with American cigarets, since my superior would not authorize such purchase.

All aliens seeking visas to the United States were sent daily to Oskar-Helene Heim for a large roentgenogram of the chest. The addition of fifty or more of this group daily to the already long line of ill patients in the bombed-out hospital corridors awaiting their appointments created many unpleasant incidents. This, in spite of the fact that these aliens and displaced persons were placed at the head of the line or even taken into the x-ray room first. I have personally witnessed these displaced persons cursing and striking the stretcher patients with canes, simply because they were Germans. It was not a happy picture. All costs of this laboratory work were paid for by the local German population in Berlin, and not by those securing the examinations, nor by the State Department, nor by the United States Public Health Service. One month the burgomaster of Zehlendorf refused to pay the bill, and since the whole program would have collapsed, my assistant, a young German medical student, gave her entire life savings to Professor Boenig so that he could meet the salary of his staff. She was discharged without reason two months later!

Professor Boenig and his half-starved staff could have become wealthy or at least a bit better nourished in a short time from the bribes offered by some of these displaced persons who suspected or even knew they had tuberculosis. To the credit of Boenig and his staff, they never wavered. It was fairly common to be offered bribes of diamonds, gold, jewelry, cameras or, more important, bacon, butter, eggs and cigarets in return for a "perfect" roentgenogram of the chest. For playing the game square, Professor Boenig and his over-worked staff were roundly cursed and abused by those sent there for their free laboratory examinations. In addition, shortly before I left Berlin, Professor Boenig was given a few hours' notice to leave the hospital and cease the practice of medicine. The charge was that he had falsified his *Fragebogen*—this in spite of the fact that he had been officially cleared in the courts of the charge.

All roentgenograms taken on these displaced persons were read by myself. It would have been hazardous to trust any other local physicians. In correlating the physical and roentgen findings of several thousand examinations, it became evident what every one knows—that the stethoscope has absolutely no place in the diagnosis of pulmonary tuberculosis. When one is confronted with this class of person, symptoms are of no value, for they admit nothing and deny everything. Thus, left with a serial study of roentgenograms as a sole criterion of diagnosis (laboratory facilities, tuberculin testing, animal inoculation, gastric washings and so forth are impossible to procure or carry out) one must necessarily defer a high percentage of cases.

Deferring such cases for future examination was a particularly heart-breaking task. Threats of suicide and physical violence were common, as were threats of political pressure to have me ousted from my position. Many of these persons came into Berlin from the Russian zone at great personal peril to themselves and families. They had to carry food and their entire belongings with them, since they never for a moment imagined that they would not pass the physical examination and would therefore have to return to their former homes. They bitterly resented a physical examination because they already had a "paper" for which they had paid a pretty penny to prove that they were healthy. For some, deferment meant a trip back into the Russian zone. For women, many of whom had suffered mass rape at the hands of the Russians, it was like a death sentence. Since none of these people bothered to put by food or wood or fuel, it literally meant sending them back to nothing. In only a few instances was it possible to procure food and temporary lodging at the local UNRRA camps until sufficient time had elapsed for another roentgenogram, and then only if the subjects were Jewish. From what I could observe, the Catholics, Protestants and those of mixed marriage were left to shift for themselves. Having no one to take care of them in this situation, they could only slip back into the cesspool of human misery —to spread their tuberculosis. Jewish organizations rallied to the need of their people and provided a tuberculosis sanatorium in Switzerland.

If we are to prevent the spread of pulmonary tuberculosis to our shores, I believe the following measures would seem both sensible and practical:

1. All aliens seeking entry to this country should be given a thorough physical examination by a qualified physician who understands pulmonary tuberculosis and who has had some training in reading roentgenograms so that he will not be at the mercy of local consultants. This physician should be interested enough in his position that he will examine the disrobed patient himself and not be satisfied with looking into a bundled-up applicant's mouth after inquiring as to the number of children in the family or—which is worse—delegating the whole job to a Public Health nurse who cannot even speak the language of the applicant!
2. All persons should have roentgenograms of their own chest as an integral part of a physical examination. The stethoscope has no place in an examination of the chest of these patients.
3. Establish with Army or other official agencies a number of controlled hospital beds with available laboratory facilities for sputum analysis, gastric washings, etc., for these deferred cases. This would reduce the hardships attendant on the long waiting period for a serial roentgenographic study.
4. Settle for once and all time, by regulation or education, in the mind of the examining doctor the fact that old persons can have active tuberculosis and that age, per se, does not protect them from having it or spreading it.
5. As an alternative, change the existing immigration laws as they affect displaced persons. Let them all enter the country *with the proviso that they enter institutions immediately.* Since we are going to have to feed them no matter where they are, the taxpayer seems to be involved either way.

F. KENNETH ALBRECHT, M.D., Director
Tuberculosis Control Division
Kansas State Board of Health
Topeka, Kansas

Council on Medical Education and Hospitals

APPROVAL OF THE AMERICAN BOARD OF PREVENTIVE MEDICINE AND PUBLIC HEALTH

During the past year the American Board of Preventive Medicine and Public Health completed its organization and was officially approved by the Advisory Board for Medical Specialties and by the Council on Medical Education and Hospitals of the American Medical Association on Feb. 8, 1949. This board is the seventeenth examining board in the specialties to be approved by the Council.

The first meeting of the Board will be held in Washington, D. C., April 25-26, 1949, to review applications submitted by the Interim Board on Preventive Medicine and Public Health comprising the surgeons general of the Army, Navy, Air Forces and Public Health Service. At this meeting also consideration will be given to the Founders' Group. The first examination of the Board will be held on May 14-16, 1949, in Washington, D. C.

The chairman of the Board is Dr. Walter L. Bierring, Des Moines, and the secretary-treasurer, Dr. Ernest L. Stebbins, 615 North Wolfe Street, Baltimore.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

NATIONAL BOARD OF MEDICAL EXAMINERS

National Board of Medical Examiners: *Parts I and II.* Various Centers. June 20-22, Sept. 12-14. *Part II.* April 25-26. Exec. Sec., Mr. E. S. Elwood, 225 S. 15th St., Philadelphia 2.

EXAMINING BOARDS IN SPECIALTIES

American Board of Anesthesiology, Inc. *Written.* Various Centers. July 15: Final date for filing application is April 15. *Oral.* April 10-14 and Oct. 16-20. Sec., Dr. Curtiss B. Hickcox, 745 Fifth Ave., New York 27.

American Board of Dermatology and Syphilology: *Oral.* New York City, April 1-3. Sec., Dr. George M. Lewis, 66 East 66th Street, New York 21.

American Board of Internal Medicine: *Oral.* Philadelphia, June 1-3. *Written.* Oct. 17. Final date for filing application is May 1. Asst. Sec.-Treas. Dr. W. A. Werrell, 1 Main St., Madison 3, Wis.

American Board of Neurological Surgery: *Oral.* Chicago, June 1949. Sec., Dr. W. J. German, 310 Cedar Street, New Haven, Conn.

American Board of Obstetrics and Gynecology, Inc.: *Oral.* Chicago, May 8-14. Final date for filing application is April 1. Sec., Dr. Paul Titus, 1015 Highland Building, Pittsburgh 6.

American Board of Ophthalmology: *Oral.* New York, June 11-15; St. Louis, Oct. 15-19; Boston, December. Sec., Dr. S. J. Beach, 56 Ivie Rd., Cape Cottage, Maine.

American Board of Orthopaedic Surgery. *Part I.* New York City, April 22-23; Atlanta, Ga., April 29-30; Indianapolis, May 6-7 and Denver, May 13-14. *Part II.* New York City, Jan. 1950. Final date for filing application for Part II is Aug. 15. Address: Dr. Francis M. McKeever, 1136 W. 6th St., Los Angeles 14, Calif.

American Board of Otolaryngology: New York, May 11-14; Chicago, Oct. 4-7. Sec., Dr. D. M. Lierle, University Hospital, Iowa City.

American Board of Pathology: Boston, April 12-13. Sec., Dr. Robert A. Moore, 507 S. Euclid Ave., St. Louis 10, Mo.

American Board of Pediatrics: *Oral.* Baltimore, May 7-9. Exec. Sec., Dr. John McK. Mitchell, 6 Cushman Rd., Rosemont, Pa.

American Board of Physical Medicine. Atlantic City, June 4-5. Sec., Dr. R. L. Bennett, 30 N. Michigan Blvd., Chicago.

American Board of Plastic Surgery: Examinations are given in June and November of each year in the home town of applicants. Sec., Treas., Dr. Louis T. Byars, 400 Metropolitan Bldg., St. Louis, Mo.

American Board of Preventive Medicine and Public Health: Washington, D. C., May 14-16. Sec.-Treas., Dr. Ernest L. Stebbins, 615 North Wolfe St., Baltimore.

American Board of Psychiatry and Neurology, Inc. December, New York City. Sec., Dr. F. J. Braceland, 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Radiology. Atlantic City, June 2-4. Sec., Dr. B. R. Kirklin, 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Surgery: *Written.* Various Centers, October. Final date for filing application is July 1. Sec., Dr. J. Stewart Rodman, 225 S. 15th St., Philadelphia.

American Board of Urology: Feb. 1950. Sec., Dr. Harry Culver, 7935 Sunnyside Road, Minneapolis 18, Minn.

BOARDS OF MEDICAL EXAMINERS

Alabama: *Examination.* Montgomery, June 28-30. Sec., Dr. D. G. Gill, 519 Dexter Ave., Montgomery.

Arkansas: * Little Rock, June 9-10. Sec., Dr. L. J. Kosminsky, Texarkana. *Eclectic.* Little Rock, June 9-10. Sec., Dr. C. H. Young, 1415 Main St., Little Rock.

California: *Examination.* San Francisco, June 20-23. Sec., Dr. Frederick N. Scatena, 1020 N St., Sacramento.

Colorado: * *Endorsement,* Denver., April 5. *Written,* Denver, June 20-22. Sec., Dr. W. W. King, 831 Republic Bldg., Denver 2.

Delaware: Dover, July 12-14. Sec., Dr. J. S. McDaniel, 229 South State St., Dover.

District of Columbia: * *Written,* Washington, May 9-10. Sec., Dr. George C. Ruhland, 4130 Municipal Bldg., Washington.

Florida: * *Examination,* Jacksonville, June 26-28. Sec., Dr. Frank D. Gray, 12 N. Rosalind Ave., Orlando.

Georgia: *Examination.* June 8-9, Atlanta and Augusta. *Reciprocity.* Atlanta, June. Sec., Mr. R. C. Coleman, 111 State Capitol, Atlanta.

Guam: *Endorsement.* Agana, Last Friday of each month. Sec., Capt. C. K. Youngkin, Dept. of Public Health, Guam. % F.P.O., San Francisco, Calif.

Hawaii: * *Examination.* Honolulu, July 11-14. Sec., Dr. S. E. Doolittle, 881 S. Hotel St., Honolulu.

Idaho: Boise, July 11-13. Sec., Miss Estella S. Mulliner, Bureau of Occupational Licenses, 355 State House, Boise.

Illinois: Chicago, April 12-14. Supt. of Registration, Mr. Fred W. Ruegg, Capitol Bldg., Springfield.

Indiana: *Examination.* Indianapolis, June 21-23. Sec. Board of Medical Registration and Examination. Dr. Paul R. Tindall, 416 K. of P. Bldg., Indianapolis.

Iowa: * *Examination.* Iowa City, June 13-15. Sec., Dr. M. A. Royal, 506 Fleming Bldg., Des Moines.

Kansas: Kansas City, June 1-2. Sec., J. F. Hassig, 905 North 7th St., Kansas City, Kans.

Kentucky: *Examination.* Louisville, June 15-17. Sec., Dr. Bruce Underwood, 620 S. 3rd St., Louisville 2.

Maryland: *Examination.* Baltimore, June 21-24. Sec., Dr. Lewis P. *Gundry, 1215 Cathedral St., Baltimore.* *Homeopathic.* Baltimore, June 14-15. Sec., Dr. John A. Evans, 612 West 40th St., Baltimore.

Minnesota: * Minneapolis, April 19-21. Sec., Dr. J. F. Du Bois, 230 Lowry Medical Arts Bldg., St. Paul 2.

Mississippi: Jackson, June 21-22. Asst. Sec., Dr. R. N. Whitfield, State Board of Health, Jackson.

Missouri: *Examination.* St. Louis, May 30-31 and June 8-10. Exec. Sec., Mr. *John A. Hailey, Box 4, Jefferson City.*

Montana: Helena, April 4-6. Sec., Dr. O. G. Klein, First National Bank Building, Helena.

Nebraska:* *Examination.* Omaha, June 6-8. Dir., Bureau of Examining Boards, Mr. Oscar F. Humble, 1009 State Capitol Building, Lincoln 9.

Nevada: Carson City, May 2. Sec., Dr. G. H. Ross, 112 N. Curry Street, Carson City.

New Jersey: *Examination.* Trenton, June 21-24. Sec., Dr. E. H. Hallinger, 28 West State Street, Trenton 8.

New Mexico: * Santa Fe, April 11-12. Sec., Dr. V. E. Berchtold, 141 Palace Ave., Santa Fe.

New York: Albany, Buffalo, New York and Syracue, June 28-July 1, Sec., Dr. Jacob L. Lochner, 23 South Pearl St., Albany.

North Carolina: *Endorsement.* Pinehurst, May 9. *Examination.* Raleigh, June 23-25. Sec., Dr. Ivan Procter, 226 Hillsboro St., Raleigh.

North Dakota: * *Written,* Grand Forks, July 5-7. *Reciprocity,* Grand Forks, July 8. Sec., Dr. C. J. Glaspel, Grafton.

Ohio: *Endorsement.* Columbus, April 5. *Written.* Columbus, June. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.

Oklahoma: * Oklahoma City, June 8-9. Sec., Dr. Clinton Gallaher, 813 Graniff Bldg., Oklahoma City.

Oregon: * *Endorsement.* Portland, April 29-30. *Examination.* Portland, July. Exec. Sec., Mr. Howard I. Bobbitt, 609 Failing Bldg., Portland.

Pennsylvania: *Examination.* Philadelphia and Pittsburgh, July. Acting Sec., Mrs. B. G. Steiner, 351 Education Bldg., Harrisburg.

Puerto Rico: San Juan, Sept. 6-10. Sec., Dr. Luis Cueto Coll, Box 3717, Santurce.

Rhode Island:* *Examination.* Providence, April 7-8 and July 7-8. Chief, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

South Carolina: *Examination.* Columbia, June 27-29. *Endorsement.* Columbia, March 7, April 4, May 2, June 27-28, Aug. 1, Sept. 5 and Oct. 3. Sec., Dr. N. B. Heyward, 1329 Blanding St., Columbia.

South Dakota: * *Examination.* Pierre, July 19. Sec., Dr. G. J. Van Heuvelen, Capitol Bldg., Pierre.

Texas: *Examination.* Austin, June 16-18. Sec., Dr. M. H. Crabb, 209 Medical Arts Bldg., Fort Worth 2.

Utah: *Examination.* Salt Lake City, July. Sec., Dept of Registration. Miss Rena B. Loomis. 324 State Capitol Bldg., Salt Lake City.

Virginia: *Examination.* Richmond, June 17-18. *Reciprocity.* Richmond, June 16. Dr. K. D. Graves, 631 First St., S.W., Roanoke.

Washington: * Seattle, July. Sec., Mr. Edward C. Dohm, Department of Licenses, Olympia.

West Virginia: Charleston, April 7-9. Sec., Dr. N. H. Dyer, State Capitol, Charleston 5.

Wisconsin: * *Examination.* Milwaukee, June 28-30. Sec., Dr. C. A. Dawson, Tremont Bldg., River Falls.

Wyoming: Cheyenne, June 20. Sec., Dr. Franklin D. Yoder, Capitol Bldg., Cheyenne.

---

* Basic Science Certificate required.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Arkansas: *Examination.* Little Rock, May 3. Sec., Mr. L. E. Gebauer, 1002 Donaghey Bldg., Little Rock.

Colorado: *Examination.* Denver, June 1-2. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver.

Connecticut: New Haven, June 11. Exec. Asst., State Board of Healing Arts, Miss Mary G. Reynolds, 110 Whitney Ave., New Haven 10.

District of Columbia: *Examination.* Washington, April 18-19. Sec., Dr. George C. Ruhland, 4130 Municipal Bldg., Washington.

Florida: *Examination.* Gainesville, June 11. Sec., Mr. M. W. Emmel, University of Florida, Gainesville.

Iowa: *Examination.* Des Moines, April 12. Sec., Dr. Ben H. Peterson, Coe College, Cedar Rapids.

Michigan: *Examination.* Detroit and Ann Arbor, May 13-14. Sec., Miss Eloise LeBeau, 101 N. Walnut St., Lansing 15.

Minnesota: *Examination.* April 4, June and Oct. Sec.-Treas., Dr. Raymond N. Bieter, *105 Millard Hall, Univ. of Minnesota,* Minneapolis.

OKLAHOMA: April 15. Sec., Dr. Clinton Gallaher, 813 Braniff Bldg., Oklahoma City.

OREGON: Portland, June 18, Sept. 3 and Dec. 3. Sec., Mr. Charles D. Byrne, State Board of Higher Education, Eugene.

SOUTH DAKOTA: Vermillion, June 3-4. Dr. G. M. Evans, 310 E. 15th St., Yankton.

TENNESSEE: Memphis, July 8-9. Sec., Dr. O. W. Hyman, 874 Union Ave., Memphis 3.

WISCONSIN: Madison, April 2. Milwaukee, June 4. Sec., Prof. W. H. Barber, Ripon College, Ripon.

Medical Motion Pictures

MOTION PICTURES ON NURSING EDUCATION

A Selected List of Motion Pictures and Slidefilms for Nursing Education has been prepared by Loretta E. Heidgerken, R.N., Ed.D., assistant professor of nursing education, The Catholic University of America, Washington 17. It contains a brief discussion of the intelligent utilization of motion pictures and slidefilms for nursing education. Approximately 210 motion pictures are classified according to subject and title including a brief abstract of each film. The slidefilms are classified according to title only. Copies of the list are procurable on purchase (price, $1) from Audio-Visual Center, Indiana University, Bloomington, Ind.

FILM REVIEWS

Animated Hematology—Bone Marrow. 16 mm., color, silent, 1,600 feet (1 reel), showing time forty-five minutes (sound speed). Produced in 1948 through a grant from the Armour Laboratories and edited by John H. Glynn, M.D., and Florian E. Schmidt, M.D., of their professional staff, in collaboration with Robert W. Keeton, M.D.; Carroll L. Birch, M.D., and Louis R. Limarzi, M.D., Department of Medicine, University of Illinois. Procurable on loan or purchase from Armour Laboratories, 1425 West Forty-Second Street, Chicago.

This motion picture presents current knowledge of normal and pathologic bone marrow in a clear and authoritative manner. The development of the subject is arranged under appropriate headings beginning with general considerations of normal bone marrow and progressing through embryology and development of bone marrow, technic of bone marrow study and finally pathology of bone marrow.

The picture summarizes the diagnosis and treatment of disorders of the blood and blood-forming organs. Emphasis is placed on the indications for sternal marrow aspiration and the dangers and limitations of this type of examination.

This film should be especially interesting to internists, residents and interns and would serve as a valuable supplement in courses in hematology for medical and postgraduate students.

Generally speaking the photography ranges from good to excellent. Some of the photomicrographs are only fair; however, others are especially good. The production is rather long and contains a great amount of material to be absorbed in one sitting.

They Live Again. 16 mm., black and white, sound, 675 feet (1 reel), showing time eighteen minutes. Prepared in 1944 by the British Council, London. Produced by the Gaumont British Instructional Ltd. Procurable on rental or purchase from British Information Services, 30 Rockefeller Plaza, New York 20, or local office.

This is a shortened version of the British motion picture entitled "Accident Service" (reviewed in THE JOURNAL Jan. 31, 1948, p. 348, and announced in THE JOURNAL May 8, 1948, p. 213, as a motion picture added to the American Medical Association Motion Picture Library) illustrating the program at a British Rehabilitation Center for complete restoration of injured coal miners. It portrays the story of a miner from the time of his injury when he received a compression fracture of a spinal vertebra until his return to work six months later.

The patient is shown being brought out of the mine after administration of first aid. He is transported to the accident ward of a general hospital and placed in suspension in a padded sling; later he is placed in a plaster cast, which he wears for four months. The film illustrates how the social service worker sets the patient's mind at ease, how the "works" physician follows through with his case and how physical therapy is started with exercises while the patient is still in the cast and with general exercises while the patient is in bed. After one week the patient attempts to walk, and this is followed by exercises in the hospital gymnasium, by gardening and outdoor exercises.

Progress continues, and at the end of four months the patient is sent to a special rehabilitation center in the country. Here he follows a planned scheme of activities which includes recreational activities such as billiards, darts, swimming, use of the library and attendance at lectures and concerts. In conjunction with this recreation he follows a routine of corrective exercises and occupational and recreational therapy which soon makes him "strong in mind and body." The patient's progress is followed by the same group of physicians who guided his care in the hospital, and after six months he is finally dismissed "once again a useful member of the community."

This film depicts the modern developments in physical medicine and rehabilitation clearly and concisely and is, in some respects, an improvement on the longer version. It is highly recommended to all physicians interested in rehabilitation and is suitable for general audiences.

Sclerotherapy. 16 mm., color, silent, 1,600 feet (1 reel), showing time sixty-six minutes. Prepared in 1948 by and procurable on loan fom H. I. Biegeleisen, M.D., 510 Madison Avenue, New York.

This motion picture presents an injection treatment in a variety of cases: varicose veins, "lymph legs," ganglion, hernia, hydrocele, hemorrhoids, pruritus ani and pilonidal sinuses.

The presentation is not recommended for general educational purposes in that it is simply a record of some of the author's cases. There is no discussion of the pathology, diagnosis, indications or contraindications for sclerosing therapy, and end results are not clearly shown. There is a rather indiscriminate use of sclerosing solutions with no mention of the type and amount of solution used and no recognition of the limitations of this form of treatment. Some of the terminology is different from that generally used and should have been explained.

Generally speaking, photography is poor to good. In several scenes there is a poor selection of background, which appears to be a black glossy stucco wall, and the high lights are somewhat distracting. In other scenes a blood pressure apparatus can be seen in the background. Closeup pictures do not show the vein in detail or the injection technic. In a few scenes there is considerable camera movement. In some cases the camera angles are not well selected and the physician's hands or arms obstruct the field. The film is much too long. A great amount of the material could be telescoped considerably. It is difficult to evaluate the end results since there is a variation of exposures in the "before and after" pictures. Several follow-up pictures are overexposed.

The Function of the Ear in Health and Disease. 16 mm., color, sound, 1,225 feet (1 reel), showing time thirty-two minutes. Prepared in 1948 and produced by H. G. Kobrak, M.D., Ph.D.; J. E. Hind, B.S., E.E., and R. B. Miller, B.A., M.D., Otological Laboratories of the Division of Otolaryngology, University of Chicago, through a grant for Postgraduate Studies in Otology by the Auralgan Research Division, Doho Chemical Company. Procurable on loan from Doho Chemical Company, 100 Varick Street, New York 13.

The film begins with a brief historical review of the early anatomists who described the hearing mechanism and the early physiologists who described its function.

The actual vibrations of the tympanic membrane and ossicular chain in response to sound vibrations have been photographed with the use of stroboscopic illumination consisting of an interruption of the light beam which produces an illusion of slow motion. Several types of ear diseases are depicted, in some of which there is interference with the vibratory movements of the ossicular chain. The response of the hearing mechanism to a hearing aid is demonstrated, and the response of the tympanic membrane and ossicular chain to orchestral music has been photographed.

The clinical material is interesting but incomplete from the point of covering the important types of hearing loss. Some of the labeling could be improved by placing the labels at one side of the illustration rather than over the structure. The film should be of particular interest to otologists; however, it is suitable for showing to general practitioners, medical students, nurses and laymen interested in problems of hearing.

The difficult photographic problems involved in this picture are well resolved by the author.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1938 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Specialization in General Practice of Medicine. R. R. Kracke.—p. 124.

Antibacterial Agents in Viral Respiratory Infections.—McLester and his associates point out that the variable treatments given to patients with febrile diseases of the respiratory tract often include sulfonamide compound, penicillin, or both, despite the fact that neither of these antibacterial agents has any theoretic value in a virus disease. They hesitated to ignore a generally followed therapeutic custom in the treatment of the patients under their supervision at the Jefferson-Hillman Hospital in Birmingham, but decided to analyze the results obtained in 569 patients who were treated for disorders of the upper respiratory tract during the three years from 1945 to 1947, inclusive. They conclude that sulfonamide compounds and penicillin are of no value in the primary treatment of infections of the respiratory tract that are variously called cold, grip, influenza, viroid, nasopharyngitis, acute bronchitis, etc. They have no data on the effectiveness of the drugs in the prevention of complications but conclude that leukocytosis alone is not an indication of the presence of a complication that indicates treatment with these agents. In view of this lack of therapeutic value, plus the known dangers of the drugs, they felt that these antibacterial agents should be given to patients with infections of the respiratory tract only when there is reasonable evidence of infection with bacteria sensitive to such therapy.

*Acute Myocardial Infarction: Detailed Study of Dicumarol Therapy in 75 Consecutive Cases. H. Greisman and R. M. Marcus.—p. 600.

Neurologic Manifestations of Digitalis Toxicity.—Batterman and Gutner point out that the involvement of the central nervous system in digitalis intoxication has been recognized and frequently reported in the literature. They cite various types of visual disturbances, vertigo, headache, drowsiness, malaise, irritability and convulsions. They report observations on 10 patients who exhibited peripheral and cranial nerve symptoms due to overdosage with digitalis products. These complaints occurred in approximately 9 per cent of the patients manifesting toxicity from digitalis. The gastrointestinal symptoms have generally been considered the most typical of digitalis toxicity, but the authors have gained the impression that neurologic disturbances not only may occur earlier than the gastrointestinal symptoms, but may also be the only manifestation of digitalis toxicity. The neuralgic type of pain usually involved the lower third of the face simulating the syndrome of trigeminal neuralgia. The pain was characterized usually as a dull aching in the teeth or as a sharp and stabbing pain throughout the mandible or maxilla, or both. Other areas involved with typically neuralgic "shooting pains" were the upper extremity, lower lumbar area with posterior thigh radiation, and calf muscles. Parasthesias, such as tingling in the fingers and burning sensations in the feet, were also observed. The type of digitalis preparation administered apparently played no role in the occurrence of these neuralgic complaints. Toxic manifestations were noted with digitalis leaf, digitoxin, digoxin, gitalin and squill from Urginea maritima and that from Urginea indica. It is probable that the other cardiac glycosides when used in toxic doses will produce the same type of toxicity.

Dicumarol® Therapy in Myocardial Infarction.—Greisman and Marcus used dicumarol® in the management of 75 consecutive ward patients with acute myocardial infarction. The mortality rate was 9 per cent and the incidence of thromboembolic lesions was 4 per cent. These results reveal a decided improvement over the results obtained in a control series of 100 patients with acute myocardial infarction treated with conventional therapy. In the latter series there was a mortality rate of 35 per cent and an incidence of thromboembolic lesions of 21 per cent. There were no serious complications attributable to the use of dicumarol.®

*Neurologic Sequelae in Macrocytic Anemia of Gastrointestinal Origin Following Folic Acid Therapy. L. M. Meyer.—p. 811.

Hemolytic Anemia with Hemoglobinuria.—During the past ten years Stats and his co-workers had an opportunity to study a large number of cases of hemoglobinuria. Four categories were encountered, namely, the Marchiafava-Micheli syndrome of paroxysmal nocturnal hemoglobinuria, cases caused by cold hemagglutinins, or by drugs and an idiopathic variety. They stress the importance of spectroscopy of plasma and urine and cite the main characteristics and differentiation of the absorption bands for the common hemoglobin derivatives. Exclusive of cases of chronic disease (mainly the Marchiafava-Micheli syndrome), hemoglobinuria was of short duration. The detection of persistent hemosiderinuria in the diagnosis of the Marchiafava-Micheli syndrome and the generally unexplored hemosiderinuria of the other hemoglobinurias are important. The relatively infrequent occurrence of serious impairment of renal function, especially in the chronic hemoglobinurias, is also pointed out. The authors indicate the serologic tests which should be performed in cases of hemoglobinuria in order to arrive at an accurate diagnosis. When anemia supervened, large and frequent blood transfusions were required. The authors believe that splenectomy is contraindicated in the hemoglobinemias or hemoglobinurias. In view of the reactions which followed blood transfusions in the Marchiafava-Micheli syndrome, a minimal number of transfusions should be given in such cases.

Neurologic Sequelae in Anemia After Folic Acid Therapy.—Meyer presents the case of a man, who at the age of 16, in 1926, was treated for macrocytic hyperchromic anemia, which developed as the result of ulcerative colitis. At this time the anemia responded to liver therapy. Repeated recurrences of macrocytic anemia after intestinal disturbances between the years 1928 to 1939 responded moderately well to diet and oral and parenteral liver therapy. In 1939 the patient was subjected to resection of the terminal ileum and ascending colon and regional ileitis was detected in the surgical specimen. A year later the patient again had hyperchromic anemia which responded to injection of liver extract. The injections were followed by severe urticaria and occasionally by vasomotor collapse. After that the patient's blood status was maintained for several years with blood transfusions, but these too caused febrile reactions. Treatment with folic acid for thirteen months was followed by the development of peripheral neuritis and combined system disease. Successful desensitization to liver extract and treatment with this drug resulted in complete remission of the neurologic disease and return to health.

Venous Thrombosis and Pulmonary Embolism in Tuberculosis.—Zahan and Peirce say that as the result of the recent wave of adverse criticism directed against bed rest as a therapeutic method, the surgeon, cardiologist, psychiatrist, obstetrician and, more recently, the phthisiologist have all deprecated its widespread use. This revolt against one of the oldest and most widely accepted therapeutic measures was occasioned by the loss of life caused by pulmonary embolic accidents. The danger of thromboembolism has been used by some internists and phthisiologists as an argument against the application of strict bed rest in the treatment of tuberculosis. A review of 3,672 autopsies at Fitzsimmons General Hospital of which 1,700 were on tuberculous subjects reveals an uncorrected incidence of thromboembolism in the tuberculous group of 2.1 per cent and a corrected incidence of 1.5 per cent. This incidence is less than one fifth of the figures reported in the literature for nontuberculous diseases. From this the authors deduce that the incidence of death from embolism is so low in tuberculosis as not to constitute a contraindication to treatment with strict bed rest.

Treatment of Superficial Corneal Injuries. A. R. Sherman.—p. 1467

Results of Corneal Transplantation.—Owens and his associates point out that statistical analysis of the results of corneal transplantation has been difficult because of the lack of a sufficiently large number of cases in any one clinic. To overcome this difficulty the American Academy of Ophthalmology made arrangements for a group of clinics to pool their material. Data have been collected on 417 corneal transplant operations. The graft remained clear in 36.5 per cent of the cases. The percentage of clear grafts varied greatly with the cause of the corneal opacity. The best results were obtained in cases of keratoconus (65.2 per cent), hereditary dystrophy (58.8 per cent), interstitial keratitis (49.0 per cent) and nonspecific inflammatory scars (46.9 per cent). Poor results were obtained in cases of active keratitis or corneal ulcer (23.1 per cent), scars from chemical burns (20.8 per cent), trauma (18.2 per cent) or gonococcus ulcers (8.7 per cent). The larger the size of the cornea and the greater the extent of corneal vascularization, the less were the chances of obtaining a clear graft. Of 229 patients with preoperative visual acuity of 20/200 or less, 36.2 per cent obtained a postoperative vision of 20/100 or better. The visual results after corneal transplantations in patients with preoperative visual acuity of 20/100 or better do not warrant the risk of operation.

Diphtheria in U. S. Troops in Europe.—Schulze reports the results of the Schick test and Schick test control performed on 42,171 U. S. soldiers in the European theater during the period from December 1946 to February 1947. About 30 per cent of the persons aged less than 35 years were Schick positive or combined reactors. There was a definite rise in the percentage of Schick-positive persons from the lower to the higher age groups. This was due to a smaller proportion of persons in the higher age groups who were immunized in childhood, because of a longer interval in the older age groups during which immunity acquired in childhood could have worn off, or a reduction of the frequency of booster action because of the more sedentary habits of older age groups. Reactions to the control material occurred with the same frequency in the Schick-negative and Schick-positive group. There was an increase in the proportion of pseudo and combined reactors from the lower to the higher age groups. Schick-positive and Schick-positive combined reactors were immunized with fluid, toxoid preserved with formaldehyde, according to the following schedule: 0.1 cc., 0.5 cc., 1.0 cc. and 1.0 cc. The 0.5 cc. dose was given two days after the 0.1 cc. test dose. The other doses were given at three week intervals. In Schick-positive-control negative persons severe reactions consisting of local edema and induration more than 6 cm. in diameter or a marked constitutional reaction with a temperature over 101 F. occurred in 3.1 per cent of those taking the first dose and less frequently thereafter. Reactions in the Schick-positive-control positive group were about three times as frequent. During the twelve month period April 1947 to March 1948, following the program the diphtheria rate was 0.7 per thousand as compared with a rate of 4.8 for the twelve month period immediately preceding the program. Practically all cases that have occurred since the completion of the program were in those who had not been immunized at all or had not completed the immunization series because of administrative neglect. Diphtheria immunization of adults with fluid toxoid according to the schedule given is a practical and safe procedure.

Streptomycin in Collapse Therapy.—Steele and Murphy administered 0.75 Gm. to 2.0 Gm. of streptomycin daily in three divided doses in twenty-four hours to 17 patients, 13 women and 4 men between the ages of 17 and 54 years, with predominantly exudative pulmonary tuberculosis, in preparation for collapse therapy. The disease of 13 of these patients was progressive when treatment with streptomycin was instituted. The average preparatory period of treatment with streptomycin was 78.8 days. Twelve patients were prepared for thoracoplasty, 3 for intrapleural pneumothorax and 2 for extrapleural pneumonolysis. In addition to the preparatory period, all patients received streptomycin during and after the institution of collapse therapy. Streptomycin not only prepared the exudative lesions for collapse therapy but also halted the progression of the disease in 13 of the 17 patients. Without its use most of the patients would never have been favorable candidates for collapse therapy and some would probably have died from progression of their disease.

Postbronchoscopic Increase of Tuberculosis.—According to Coates, in a series of 473 bronchoscopies in 233 patients who had tubercle bacilli in their sputum at some time during their residence in the Trudeau Sanatorium, the incidence of roentgenographic increase of pulmonary tuberculosis in the two months immediately following bronchoscopy was no greater than that in other two month periods before bronchoscopy. Bronchoscopic observations in 73 bronchoscopies followed within two months by roentgenographic increase, as compared with those in 400 cases not showing such a postbronchoscopic increase, revealed essentially the same percentage of active endobronchial tuberculosis in the two groups. In a group of 59 patients who had roentgenographic evidence of increase of disease within two months after bronchoscopy, the percentage of cases of far advanced disease was no greater than in the remaining 174 patients who showed no such postbronchoscopic increases. The effect of progression of the disease before bronchoscopy on the course immediately after bronchoscopy was investigated in the group of 149 patients undergoing bronchoscopy only once. Thirty-five of these patients showed roentgenographic evidence of progression within two months preceding bronchoscopy, while 114 did not. In these two groups the incidence of roentgenographic increases in the two months following bronchoscopy was essentially the same.

Anatomic Changes Following Streptomycin.—Auerbach and Stemmermann performed necropsies on the cadavers of 7 men between the ages of 19 and 53 with pulmonary tuberculosis, who had died after receiving streptomycin for sixty to two hundred and ten days. The postmortem observations revealed that streptomycin is an aid in the healing of tuberculosis. It has a much greater effect on tuberculous foci in the superficial surfaces than on the foci in solid organs. The perifocal reaction surrounding acinous foci is rapidly and extensively resolved, thus diminishing the amount of fibrosis which would ordinarily occur in this zone. Tuberculous foci in the lung show a greater tendency to heal than in untreated patients. The contrast of the action of the drug on solid organs and superficial surfaces is best seen in acute generalized miliary tuberculosis, in which the healing changes in solid organs lag behind those in the lungs. The greatly decreased incidence of ryngeal and intestinal tuberculosis is also attributed to greater ling on superficial surfaces. The highly satisfactory clinical onse observed in tuberculous meningitis seems to give her evidence of the action of streptomycin on superficial surfaces. Streptomycin does not appear to prevent dissemination of the disease either through the bronchial or lymphohematogenous routes, but, after such disseminations occur, the drug stimulates their more rapid healing.

Decompression Operation for Hydrops of Labyrinth in Ménière's Disease.—Lempert points out that both the clinical picture and the histologic aspects of Ménière's disease permit the conclusion that it is a disease limited to the internal ear and that both the vestibular and the cochlear portion thereof are involved. It is therefore logical to assume that by effecting degeneration of both the vestibular and the cochlear part of the endolymphatic labyrinth in a case of monaural Ménière's disease, and thus preventing the recurrence of endolymphatic hydrops, it should be possible permanently to relieve the patient of the vertigo, which is vestibular in origin, and the tinnitus, which is probably of cochlear origin. The author describes a new technic for effecting atraumatic and aseptic degeneration of the endolymphatic labyrinth. The removal of the stapes and the round window membrane without traumatizing either the temporal bone or the endolymphatic labyrinth when executed under sterile precautions results in aseptic degeneration of the entire endolymphatic labyrinth and of the organ of Corti. Of the 10 patients who were operated on with this technic, 9 were freed from both vertigo and tinnitus. One was free of vertigo but not of tinnitus, though the intensity of the tinnitus even in this case has greatly diminished.

Nonoperative Treatment of Perforated Peptic Ulcer.—Cohn and Mathewson point out that although surgical closure of the perforation is usually successful, the treatment of the patient with long-standing perforation or of one with generalized peritonitis is far from satisfactory. They reviewed the records of 265 patients with perforated ulcer, who were treated at the San Francisco Hospital. Ten patients with proved perforated ulcers recovered without operation on the following regimen: constant gastric suction through a Levine tube, nothing by mouth, parenteral dextrose solution and vitamins and sedation. Antibiotics were used in only 3 cases. In all cases except one, free air was demonstrable by roentgenogram. In this patient an abscess was found walled off by the liver at the site of perforation. In the experience at the authors' hospital, free air is present in 85 to 90 per cent of all cases of perforated ulcers. Its absence suggests that the perforation has been rapidly sealed off. If no free air is present in a patient who is clinically improving, they believe it safe to start out with the nonoperative treatment. The authors cite patients who recovered without operation and those who died without operation and those who died after operation. The over-all mortality rate in the 265 patients was 12 per cent, whereas the operative mortality rate was 6.4 per cent. They believe it justifiable to delay operation in all those patients in whom peritonitis is apparently becoming localized and who seem to be improving clinically. One would be encouraged in this stand if no free air could be demonstrated in the peritoneal cavity by roentgenogram.

Side Effects of Antihistaminic Drugs.—Holtkamp and his associates observed side effects from the use of diphenhydramine hydrochloride (benadryl®) and tripelennamine hydrochloride (pyribenzamine®). Usually these side effects consisted of drowsiness, dizziness or nervousness, but more severe reactions such as "benadryl jag," unconsciousness, narcolepsy and epileptiform movements have been seen. Recently, a combination of 25 mg. diphenhydramine hydrochloride and 100 mg. aminophylline (per tablet), hydryllin,® has been added to the antihistaminic drugs. The present study was made to obtain a more adequate basis for the comparison of the side effects caused by these three drugs. The drugs were given in therapeutic dosage to healthy college students. It was found that mental ability, reaction time and minimum distance of two point discrimination were appreciably altered by these drugs in over half the subjects tested. Tripelennamine caused a greater number to show a decrease in efficiency than did diphenhydramine, but the latter occasionally caused decreases of considerably greater magnitude. Hydryllin® caused an increased efficiency in a majority of the subjects but adversely affected a few. A patient who first takes these drugs should be observed carefully and should be warned of the dangers inherent in his reduced ability to react quickly. These factors are especially important in driving an automobile.

Hemolysin Associated with Mumps Virus.—Morgan and his co-workers say that during experiments by some of the members of their group hemolysis was observed in suspensions of chicken erythrocytes exposed at 37 C. to amniotic or allantoic fluids derived from chick embryos infected with mumps virus. The results of systematic studies of this hemolytic factor are described in the present communication. A factor capable of causing hemolysis of the erythrocytes of man, chicken and sheep occurs in the amniotic and allantoic fluids of chick embryos infected with the virus of mumps. The hemolysin has not been found in normal fluids or in those infected with PR8 or Lee B strains of influenza virus. The hemolysin is definitely inhibited by the serum of man and monkey convalescent from mumps, but only slightly by the serum of the acute phase. The hemolysin is almost completely inactivated at 50 C. after ten minutes. It exhibits maximal activity at 37 C. and is completely inactive at 4 C. A p_H range from about 7.0 to 8.0 allows for maximum activity. Adsorption and elution of the hemolysin with red blood cells has been demonstrated. After elution of the hemolysin, the red blood cells exhibit an increased osmotic fragility. Similar treatment of red cells with influenza virus did not alter this property.

Diagnosis of Pulmonary Stenosis by Angiocardiography.—Carson and his associates feel that angiocardiography is of value in infants and children who are too small for cardiac catheterization. The tautograph developed by one of the authors (Scott) makes ten radiographic exposures within ten seconds. Each patient fasts for at least four hours before the procedure. Infants and children are given a general anesthetic, older patients a local anesthetic. In patients with cyanotic heart disease and polycythemia, subcutaneous fluids are administered preoperatively and oxygen is given concomitantly with the anesthetic. The patient is placed on the tautograph, and the antecubital vein is isolated. The distal end is ligated and a cannula is inserted into the proximal end and tied in place. A slow intravenous drip of isotonic sodium chloride solution is begun through a three way stopcock to insure patency of the cannula. A few minims of 70 per cent iodopyracet is injected and, if after several minutes no reaction has occurred, the final injection is made. Infants 3 months to 2 years of age receive 10 to 18 cc. of iodopyracet, and older children 20 to 40 cc. The injection must be made as rapidly as possible in order to obtain a sufficiently dense concentration. In the tetralogy of Fallot (1) an interventricular septal defect is indicated when iodopyracet flows directly from the right ventricle into the left ventricle; (2) simultaneous opacification of the aorta, pulmonary conus and pulmonary arteries indicates the presence of an overriding aorta with the iodopyracet flowing simultaneously into both the aorta and the pulmonary conus from the right ventricle; (3) enlargement of the right ventricle is seen; (4) the decreased caliber of the pulmonary arteries is visualized. This last observation will differentiate tetralogy of Fallot from Eisenmenger's complex, in which pulmonary arteries of normal or unusually large size are seen. In cases of nonfunctioning right ventricle with tricuspid stenosis opaque material enters the right auricle from the superior vena cava. None enters the right ventricle, but instead it can be seen entering the left auricle and then an enlarged left ventricle. Then there is simultaneous visualization of the aorta, and if pulmonary stenosis is present, small pulmonary arteries are visualized. Persistent truncus arteriosus with stenotic pulmonary arteries will show a large right ventricle; a large interventricular septal defect is indicated by rapid opacification of the left ventricle in the second or the third roentgenogram; in these same roentgenograms a single large vessel is seen emerging from the region of the ventricles and, because opacification of this vessel occurs at the same time the left ventricle begins to be visualized, it is likely that the truncus overrides the septal defect; no pulmonary conus is seen, but small pulmonary arteries can be seen arising from the single large truncus.

Streptomycin in Pertussis.—Only patients having uncomplicated whooping cough were included in this study by Leichenger and Schultz. The patients were assigned in rotation to one of three groups. Those in the first group received streptomycin by the aerosol route; those in the second group received it intramuscularly, and those in the third received the usual symptomatic whooping cough treatment of the Cook County Contagious Disease Hospital. The latter were considered controls. Each group comprised 8 patients. While this is a small series, daily observation of these patients gave the impression that those who received streptomycin via aerosol did much better clinically than the other two groups, despite the fact that the children had to be awakened to receive the treatment. This awakening frequently initiated a paroxysm. No toxic effects of the drug were noted with the exception of a transitory generalized morbilliform eruption which lasted two days in 1 patient who received streptomycin intramuscularly. Since there had been no previous experience with streptomycin in whooping cough, the dosage of 1 Gm. a day and the length of treatment of one week were arbitrarily decided on. The authors believe that there is sufficient evidence that streptomycin is of clinical benefit in the treatment of pertussis to justify a more extended use.

Treatment of Acute Osteomyelitis of Long Bones in Infants and Children.—Beerman shows that during the past few years the treatment of acute hematogenous osteomyelitis has changed so that the management is now chiefly medical rather than surgical. He presents observations on 7 patients and outlines a plan for the treatment. It is important to have a high degree of suspicion of the presence of the disease. Treatment is started at the earliest possible moment when a tentative diagnosis is made, or when some other diagnosis, such as cellulitis, seems likely but osteomyelitis cannot be ruled out completely. Supportive care for dehydration and pain is given. Penicillin is administered in a dosage of 50,000 units every three hours intramuscularly for fourteen to twenty-eight days or more. Orthopedic consultation is obtained, but generally the care is chiefly medical unless deep abscesses are present. Such abscesses are aspirated or drained. If the disease is of moderate duration (six to seven days), there is a great probability that surgical care will play the major role, with penicillin an essential aid but not effective as a sole agent. Beerman does not use plaster immobilization, for he feels that ordinary rest in bed is adequate splinting in cases in which only medical care is necessary. When deep abscesses are present or when extensive bone involvement is noted because of delay in diagnosis, or because of a particularly massive and virulent infection, splints are used. Weight bearing is not permitted until roentgen studies show regression of bone lesions. Roentgen examinations are recommended every one to two weeks until the bone changes are showing regression, and then every four to eight weeks until complete healing. After complete healing, the patient should be followed every six months to a year for several years by roentgen studies.

Fifty Shock Therapy Theories. H. L. Gordon.—p. 397.

Mesenteric Vascular Occlusion.—According to Rives, occlusion of the blood supply of the bowel may result from mechanical causes as in strangulation or from either thrombosis or embolism. The mortality of mesenteric vascular occlusion is extremely high because (*a*) many patients are in extremis from cardiovascular disease when it occurs and (*b*) in most others diagnosis and treatment are too long delayed. Features that aid in diagnosis are a history of a known predisposing cause, the character of the onset, the early disappearance of peristalsis in a case of suspected intestinal obstruction, the occurrence of a high degree of leukocytosis without evidence of peritonitis and the development of shock when all other evidence points toward partial obstruction. The treatment for all types of the disease should be the same because the effect on the bowel is the same and the ischemia usually progresses to infarction. Radical resection of the bowel is essential when gangrene has developed. Anticoagulant therapy may prevent mesenteric vascular occlusion and may be of value in postoperative treatment, but cannot be recommended as definitive treatment.

Acute Renal Insufficiency Due to Lower Nephron Nephrosis.—Acute renal insufficiency due to the lower nephron nephrosis or hemoglobinuric nephrosis occurs in association with intravascular hemolysis associated with transfusion reactions, blackwater fever, sensitivity to quinine and transurethral prostatectomy, as well as in the crush syndrome, nontraumatic muscle ischemia, electrical injury to muscle, heat stroke, uretero-placental damage, alkalosis from excessive vomiting, thermal burns, sulfonamide sensitivity and from various poisons, particularly carbon tetrachloride. Strauss presents data pertinent to this syndrome and 7 case histories. There is evidence that neither nitrogen retention nor acidosis is responsible for the usual fatal outcome. Fatal cases of lower nephron nephrosis often exhibit generalized and pulmonary edema at necropsy. In the absence of pulmonary edema potassium intoxication may lead to a fatal outcome. Man, unlike small animals, may survive without renal function for four or more weeks, if excessive quantities of fluids are not administered parenterally. The tubular lesion is often reparable, with spontaneous diuresis to be expected within three weeks, if the patient can be kept alive this long. Many treatments proposed for this condition fail to speed the appearance of spontaneous diuresis. Strauss outlines a regimen which consists essentially in the replacement of water loss and in the furnishing of 100 Gm. of dextrose daily. This may, in many cases, permit the patient to survive long enough to have spontaneous recovery.

Dicumarol® in Congestive Heart Failure.—Wishart and Chapman believe that thrombosis and embolism are serious threats to the life of the decompensated cardiac patient. The authors employed dicumarol® in 61 patients with congestive heart failure in order to decrease the incidence of embolic phenomena. Previously published reports indicate that in a group of cardiac patients comparable to these one may expect embolic phenomena in the form of infarcts of the lungs in at least 22 per cent. In this series, the incidence of such lesions, during the period when dicumarol® therapy was effective, was 6.5 per cent. There were no deaths attributable with certainty to massive pulmonary embolism, and only 1 death that might conceivably have been due to such an accident. On the basis of these results, it is probable that dicumarol® therapy gives protection from thrombosis and embolism to the cardiac patient when he needs it most—when he is in congestive failure.

Outlook for Elderly Mental Patients. — According to Clow it is frequently assumed that in patients in whom mental disease develops or who have recurrences of such diseases after the age of 60 the prospects of recovery are poor. This question was investigated in a group of 365 such persons consecutively admitted to a New York Hospital from 1936 to 1946. Nearly two thirds had functional reactions, which included the involutional psychoses which represented typical agitated and paranoid depressions arising in rigid personalities in response to changes in the life situation. In the remaining 35.1 per cent the usual mental and physical evidences of psychosis associated with organic impairment of the brain were present. At the time of leaving the hospital the group as a whole showed 24.1 per cent to have recovered, 19.7 per cent to be much improved, 20.3 per cent improved, 21.4 per cent unimproved and 14.5 per cent to have died in the hospital. Of the 33 patients with senile psychosis, none recovered. Of the patients with psychosis with cerebral arteriosclerosis, however, 15, or 19.7 per cent, showed substantial improvement with the ability to adjust adequately at home. Of 4 patients with organic delirium due to drugs, all recovered. In the group of 111 patients with manic-depressive disorders, 43 per cent recovered and 22 per cent improved. However, none of the 11 patients with well established dementia praecox showed great improvement. Good resources, which give security, and a favorable family situation were important factors in recovery. Age likewise seemed a factor, since those in the seventh decade showed better prospects of recovery than did those in the eighth or ninth decades.

Toxoplasmosis in Children.—Adams and his co-workers report 5 proved cases of toxoplasmosis in infants and 9 cases in which the clinical and laboratory evidence strongly suggested this diagnosis in infants and children. The most important observation in these patients has been the almost constant occurrence of internal hydrocephalus. It was present in patients with a normal or small head size as well as in macrocephalus. Convulsions were present in only 3 of the patients in sharp contrast to the incidence previously reported. Cerebral calcification occurred in 7 of the patients and chorioretinitis was present in 5. Five patients had neither of these cardinal manifestations, and 2 of these were patients in whom the toxoplasmic organism was found. This evidence strongly suggests that the diagnosis of toxoplasmosis should be suspected in the presence of internal hydrocephalus, particularly with spinal fluid changes such as elevated protein and pleocytosis. When the classical triad or tetrad of symptoms and signs of the disease is present and the result of the neutralization test is positive, the diagnosis of toxoplasmosis probably should be made, since isolation of the organism from the patient is difficult at the present time. One patient aged 2 months had a progressive jaundice from birth; it subsided gradually, but it can be the presenting complaint in a patient with congenital toxoplasmosis. Most of the patients had the onset of their illness in utero, at birth or shortly after birth. Nine of the patients are still alive, and except for 2, the chances of their living for many years are good. It seems likely that if the patient can survive the acute infection a chronic state can be reached that is compatible with life.

Replacement Transfusion in Erythroblastosis Fetalis.—Diamond treated 95 infants with erythroblastosis fetalis by replacement transfusions. The first 10 were given transfusions by various routes, two peripheral veins or the longitudinal sinus and a vein being used. The last 85 had been given transfusion only through the umbilical vein with a long bland plastic, polyethylene catheter and needle, two three-way valves being connected directly to the needle. By alternate maneuvers of first removing and next putting in blood 20 cc. at a time, the infant can gradually be exsanguinated and most of its blood volume replaced with relatively little trauma. About a pint of group O blood or group-specific blood of the Rh-negative type is used usually in replacing the infant's own blood volume. In the course of about one to one and a half hours this 500 cc. of blood replaces between 90 and 95 per cent of the infant's own circulating erythrocytes. Of the 95 infants, 20 belonged to families in which a previous child had died with erythroblastosis. In such families the statistical chance of a subsequent infant's survival is less than 10 per cent, and yet of these 20, 14 infants (70 per cent) survived and are completely well without residual damage. Two died and 4 lived but showed evidence of kernicterus later. Of the 85 infants treated by umbilical vein transfusion 65 are now living and well and show no evidence of residual damage over a period of three months, some of them right up to fifteen months. Seven patients died, but not of erythroblastosis. This mode of treatment has the advantage of ease and greater safety, and an added advantage of the earlier discharge of the patient from the hospital in seven or eight days, rather than in two to three weeks.

Feeding Agenized® Flour to Dogs.—Newell and his co-workers placed a series of dogs on a diet which contained an amount of agenized® flour approximately equal to that used in the average American diet. The results demonstrated that dogs can be fed a ration containing moderate levels (30 per cent) of commercially agenized® flour for long periods (twelve to fourteen and a half months) without having running fits or electroencephalographic abnormalities.

Effect of Rutin on Dicumarolism.—Under the experimental conditions employed by Clark, rutin does not antagonize dicumarolism in rats. Presumably the defect in the vessel walls or their supporting structures which leads to hemorrhage in dicumarolism differs from that leading to the various hemorrhagic conditions which rutin and related "vitamin P"-like substances purportedly benefit. These facts, however, need not necessarily preclude the simultaneous use of dicumarol® and "vitamin P" for their separate effects, as illustrated by a report on the favorable effects of rutin and dicumarol® in various retinal vascular disorders.

Isolation of Mumps Virus.—Killham reports a boy, aged 3, in whom a clinical diagnosis of mumps was made when the left parotid was found firm, swollen and tender. Several days later swelling appeared in the parotid on the right side. Blood was drawn the day parotitis was first observed and 5 cc. treated with sodium citrate. Because whole citrated blood had resulted in a high mortality in previous egg inoculations, the plasma was separated from the red blood cells after natural sedimentation, and the two fractions stored in solid carbon dioxide. Two weeks later 12 eggs were inoculated intra-amniotically with 0.1 cc. of the plasma, and 5 survived for harvesting. The red blood cell fraction was diluted 1:2 in infusion broth, and the mixture in 0.2 cc. amounts inoculated into 12 eggs intra-amniotically. Only 3 embryos survived. In the third egg passage, virus was detected in 4 of 8 amniotic fluids, and in almost all eggs of two subsequent passages. The cerebrospinal fluid inoculated into eggs in 0.2 cc. amounts yielded no virus in three passages, a not unexpected result, since the patient had no symptoms suggesting meningoencephalitis. Inhibition of hemagglutination and complement fixation tests identified the agent as the mumps virus.

Bilateral Ablation of Focal Area of Frontal Cortex.—Heath and Pool performed bilateral extirpation of different areas and combinations of areas of frontal cortex on 24 patients with chronic psychosis who had not responded to conventional therapy, including shock, at New Jersey State Hospital in Greystone Park. In all of the patients who showed definite improvement as a result of operation, Brodmann's areas 9 and/or 10 were included in the removal. In addition to the Greystone patients 23 private patients have been operated on. In these too, conventional treatment, including shock, had failed. All in this group had removals confined to the region of areas 9 and/or 10. Eight have been followed less than three months. Of the remaining 15, all but 2 had been institutionalized before operation for periods up to twenty-eight years; of this group 10 are now able to function at old capacity, 3 are able to be out of the institution with supervision and 2 remain institutionalized. Beneficial effects resulting from removal of areas 9 and/or 10 are constantly in the sphere of affective response, so that tensions do not accumulate, thereby making regressive reparative behavior unnecessary. Patients in whom more than two large Brodmann areas or several small cortical areas are removed will show signs of deterioration in social behavior, as occurred in the authors' case of lobotomy in which large amounts of cortex were undercut. The operation as now performed (topectomy) consists of removal of the posterior part of area 10 and the anterior part of area 9. Improvement appears to be related to site removed rather than differences in cytoarchitecture. Patients whose overt psychotic symptoms are removed by this operation show essentially the same basic personality traits as were present before the illness began. In persons with chronic psychosis affect becomes divorced from ideation to varying degrees. This seldom occurs except in cases of schizophrenia and manic psychosis. As this dissassociation increases, the prognosis with operation becomes less favorable.

Anion Exchange Resins in Treatment of Peptic Ulcers.—Impressed by laboratory and clinical reports indicating that certain of the resins take up hydrochloric acid, and looking for an antacid which would be effective without undesirable side reactions, Weiss decided to use the anion exchange resin (200 mesh) in a series of patients in whom duodenal or gastric ulcers had been demonstrated by means of roentgen rays. Forty of 44 patients had symptomatic relief in from one to eight days. Three patients with gastric ulcers had no response. One patient with a cancer had no response. The average time of roentgenologic regression of the ulcer crater in 39 successful cases was ten to fourteen days. Neither diarrhea nor constipation was observed during or after treatment with the resin.

Treatment of Rocky Mountain Spotted Fever.—Woodward and Raby treated 17 patients, 12 children and 5 adults, with Rocky Mountain spotted fever by administration of para-aminobenzoic acid. An oral dose of 8 Gm. of the sodium salt in tablet form was given to the adults initially with subsequent two-hourly doses of 3 Gm. For children the dosage was generally two thirds of that of the adults. A priming dose was administered to severely ill patients when a prompt high blood level was desired by intravenous route with a concurrent dose by mouth, the schedule thereafter being by mouth. A two hour schedule by mouth was routine, and when the determined levels of para-aminobenzoic acid in the blood were below 10 mg. per hundred cubic centimeters, the level sufficient to sterilize the blood, supplemental drug was administered intravenously. The optimum effective blood level is 40 mg. per hundred cubic centimeters, although no untoward reaction resulted from higher levels over short periods of time. The average duration of the entire febrile course was 6.8 days; the average duration of fever after the administration of the drug was 3 days and the average duration of hospitalization 11.9 days. Treatment with para-aminobenzoic acid was terminated in 9 patients after the temperature was restored to normal. There were no subsequent relapses. This procedure is not recommended if the improved clinical condition of the patient does not coincide with the drop in temperature. Para-aminobenzoic acid exerts a direct effect on the circulating rickettsiae. The bedside observation of a greatly shortened rash in 4 cases strongly points to prompt intracellular inhibition of rickettsial growth.

Syphilitic Interstitial Keratitis.—Forsyth treated 70 patients with syphilitic interstitial keratitis, 56 of whom had active interstitial keratitis, with typhoid-vaccine-induced fever and penicillin. This treatment is suitable for use in a small private hospital or rapid treatment center. All patients were treated on an ambulatory basis. The results of experiments with various-sized initial doses of killed organisms showed that the average number of hours of fever from the first typhoid vaccine injection were between four and five, if the dose was 200,000 to 300,000 killed organisms per pound of body weight. Although up to 25,000,000,000 organisms (25 cc.) were given, there was little increase in patient response to doses in excess of 12,000,000,000 organisms and, unlike smaller doses, the 12,000,000,000 organism dose may be repeated two or more times, giving an adequate febrile response on each administra*tion. All patients weighing over 65 pounds (29.5 Kg.)* were given penicillin in doses of 40,000 units each two hours for a total of eighty-five injections over a period of a week. All patients under 65 pounds of weight received 250,000 units of penicillin per 5 pounds (2.3 Kg.) of body weight in sixty injections. Forty-one of the 70 patients returned for follow-up examinations, representing 46 eyes involved with active interstitial keratitis and 20 eyes involved with inactive interstitial keratitis at the time of the treatment. Eighty-eight and three-tenths per cent useful vision was restored in 38 of these patients who had had determinations of visual acuity. The patients who had been treated within two months of the onset of their interstitial keratitis showed a 90.5 per cent return of useful vision. Results of penicillin and typhoid-vaccine-fever therapy in the treatment of interstitial keratitis are as good as the best results from any other form of therapy. Penicillin has the further advantages of a lowered incidence of toxic reactions and a shorter course of treatment. When fever therapy is used in addition to penicillin in the treatment of interstitial keratitis resolution is more prompt than when penicillin alone is used.

Borrmann Typing in Carcinoma of Stomach.—Moore and his associates direct attention to Schindler's belief that the prognosis and perhaps the therapeutic procedure for carcinoma of the stomach may be based on the Borrmann typing of tumors. *Borrmann classified gastric carcinomas as: I, sharply* demarcated polypoid carcinomas; II, sharply demarcated ulcerated carcinomas; III, partly infiltrating carcinomas, and IV, diffusely infiltrating carcinomas. On the basis of an analysis of 239 cases Schindler questioned the advisability of resection of infiltrative tumors. Since this challenges the belief that as many carcinomas as possible should be resected, the authors decided to review the records of patients treated at their clinic. The diagnosis of gastric carcinoma was made in 342 patients, and in 177 of these gastric resection was done. They conclude that the presence or absence of demonstrable metastases in regional nodes among patients subjected to gastric resection for carcinoma has a greater prognostic value than has the classification according to the Borrmann type. Borrmann's typing affects the prognosis to the extent that the limited tumors provide a proportionately large number of patients free of matastases while the infiltrating tumors are more likely to have metastasized. The presence or absence of metastases cannot be accurately determined preoperatively and no patient should be denied operation because of the type of tumor which he may be determined to have.

Streptomycin in Surgery of Pulmonary Tuberculosis.—Murphy says that the Army and the Navy have been conducting a cooperative study of the bacteriostatic action of streptomycin on the tubercle bacillus. The surgical divisions of the forty-seven participating study units were asked to determine whether streptomycin provides protection against postoperative *spread or reactivations and against the development of empyema* in patients subjected to thoracoplasty and pulmonary resection for tuberculosis. Every alternate patient subjected to thoracoplasty and every patient undergoing lobectomy or pneumonectomy was given streptomycin as a protective agent. In the beginning 2 Gm. of streptomycin per day were given by intramuscular injection, divided into five doses. On Oct. 15, 1947, the standard daily dose was reduced to 1 Gm., divided into two doses of 0.5 Gm. each at twelve hour intervals. It was desired to avoid, as far as possible, the development of resistance to the drug. Under both regimens the drug was administered for one week before and two weeks after each operation. The results of study concerning the protective action of streptomycin in 1,347 thoracoplasty stages and 129 pulmonary resections for tuberculosis are presented. It was concluded that streptomycin should not be given to the routine thoracoplasty patient but should be reserved for the occasional borderline risk patient in whom the disease is more widespread and more exudative in character than is usually considered suitable for surgery. The use of streptomycin is mandatory, however, before as well as after pulmonary resection for tuberculosis.

Displaced Intervertebral Disks.—Grant and his associates made studies on 95 patients, who had been subjected to operations on intervertebral disks. Examination by members of the orthopedic and neurosurgical staffs was followed by anteroposterior and lateral roentgenograms of the lumbar portion of the spine and the pelvis. Neurologically, the patients were examined for sensory, motor and reflex changes. The lower limbs were checked for signs of atrophy or weakness and for the presence of pain on straight leg raising. Orthopedically, the patients were examined for scoliosis, restricted mobility, paravertebral spasm or pelvic tilt. All patients were questioned as to the presence of any residual back pain or sciatic pain. The patients were also asked concerning their personal opinion of the operation. Sixty per cent of these patients were regarded as cured and were able to pursue a normal day's work without back or sciatic pain. Eighty-seven per cent of these were fully satisfied with the results of the operation. Air myelograms, while helpful, were not as accurate as desired. Oil myelography, preferably with pantopaque® (ethyl iodophenylundecylate) as the contrast medium is the method of choice and should be routinely employed. Lost or diminished achilles reflexes do not often return, nor should a patient be allowed to believe that paralyses will invariably recover after successful removal of the offending mass. Fusion of the vertebral bodies or dense bridging occurred in 6 patients, all of whom are in the group of clinically well. This change will probably develop in more as time goes on. It seems unlikely that the presence of a significant quantity of residual opaque oil in the caudal sac has any influence on the clinical result.

Cerebral Angiography in Intracranial Hematomas.—According to Kristiansen most head injuries belong to the cerebral concussion group. Dehydration by means of magnesium sulfate enemas is used both as a prevention against cerebral edema and as a treatment in patients in whom edema has developed. The symptoms in cases of cerebral edema are very similar to those of intracranial hematomas. The effect of dehydration in these patients is therefore of considerable diagnostic value. Intracranial hematomas are relatively infrequent lesions in patients with head injuries. In the series of cases observed by the author from 1937 to 1939, only 1.2 per cent of the patients presented extradural and 1.2 per cent subdural hematomas. A careful preoperative diagnosis of the nature and the site of the lesion is a prerequisite for an effective treatment. Clinically, the patient's state of consciousness is the main guide in determining whether there is to be operative intervention or not. Increasing drowsiness frequently combined with motor restlessness, stupor and finally coma, which does not recede during dehydration, present a clear indication for surgical intervention, but, before an operation can be undertaken, the nature of the intracranial lesion must be ascertained. For this percutaneous carotid angiography is found most useful. Over a period of several years, no serious complications have arisen from using this method in neurologic and neurosurgical diseases. The contrast agent is a 35 per cent solution of iodopyracet. The author presents case histories which show the different diagnostic problems presented by patients with head injuries during the first days after the accident. Without cerebral angiography the presence of the intracerebral clot will easily be overlooked. Among the cases reported by the author, there were 3 in which there was a combination of a subdural hematoma and an intracerebral hematoma. The excellent result of operative treatment on this form of intracerebral hematomas is a temptation to apply similar therapy in suitable cases of ordinary brain hemorrhages or apoplexies.

Effect of Carinamide with Heparin on Coagulation.—Since carinamide (4-carboxyphenylmethanesulfonanilide) had been used to prolong and augment the blood level of penicillin, Sirak and his co-workers decided to investigate whether carinamide might have a similar effect on heparin. The 10 patients picked at random were in the preoperative phase and their illnesses did not contraindicate the administration of heparin. The authors found that heparin in saline solution, given intravenously one-half hour after a single dose of carinamide, causes a progressive enhancement of the effect of an equal dose of heparin administered on each successive day. In 8 of 10 patients, this enhancement reached a peak in approximately three days and is manifested by a two to ten fold increase in coagulation time response to heparin. This peak is followed by a gradual return to a normal response, two to three days later. Incomplete evidence suggests that this effect may be due to the formation of a new compound and not to carinamide blockage of the renal excretion of heparin. If results can be achieved with small doses of heparin the cost of heparin therapy will be greatly reduced.

Apoplexy of Gallbladder.—Christopher and Savage report the case of a woman, aged 46, who had hypertension and in whom there occurred a large hemorrhage into the noncalculous gallbladder. They point out that hemocholecyst is the term applied by Fiessinger to massive, nontraumatic gallbladder hemorrhage. They have employed the term "apoplexy of the gallbladder." In the case reported by them there was hypertension and absence of gallstones. It is thought likely that slight bleeding may occur frequently in diseased gallbladders. If traumatic cases are excluded, massive hemorrhage from the gallbladder is almost always associated with cholelithiasis. On review of the literature 28 such cases were found to have been reported. Massive hemorrhage from a noncalculous gallbladder is rare. In addition to the case herewith presented, only 2 cases have been reported, 1 by Schnyder concerning a man, aged 72, and 1 by Fiessinger concerning a boy aged 4½ years. Hypertension has been noted in only 1 other case of massive hemorrhage, that of Hudson and Johnson, but in their case cholelithiasis was present.

Vagotomy in Duodenal Ulcer.—Weinberg and Kraus performed vagotomy in 150 patients between the ages of 20 and 69 years with duodenal ulcer. The duration of symptoms was one to thirty years. The follow-up has extended from twelve to twenty months in 40 patients, from six to twelve months in 69 patients and from one to six months in the remaining 41 patients. Of the patients 146 have remained completely well during the period of observation. Three have persistence of ulcer symptoms, and 1 died as a result of postoperative pneumonitis. The occurrence of associated undesirable effects of vagotomy, including gastric retention, diarrhea, cardiospasm and a syndrome suggestive of hypoglycemia, is unpredictable. These side effects do not seriously weigh against the value of the operation. The advantages of the abdominal approach over the thoracic approach are so decisive that the latter method has been practically discontinued. Posterior gastrojejunostomy is now performed routinely with vagotomy to overcome the relatively frequent and unpleasant complication of prolonged gastric retention following vagotomy. Because there may be intermissions of many years between active phases of the ulcer diathesis, it is too early to predict the final outcome in the patients reported. The results thus far are superior to those experienced or seen reported with other methods of surgery over a similar period.

Skin Cleansers and Protective Creams for Workmen Exposed to Mineral Oil.—Cruickshank points out that in many industrial processes the workman's skin is constantly exposed to mineral oils which are potentially harmful. Uncontaminated oils are invisible on the skin in small amounts, so that the effectiveness of their removal cannot be assessed by direct examination. This difficulty was overcome by utilizing the fact that most mineral oils produce a brilliant violet fluorescence when examined in ultraviolet light. The intensity of this fluorescence gives a measure of the amount of oil remaining and thus provides a means of comparing the efficiency of detergents. The efficacy of soap in various concentrations was first investigated. Soap powder is the most concentrated form of soap possible. Used alone this was unsatisfactory from a practical point of view in that the addition of water caused clumping and caking. This was avoided and the detergent properties of the soap greatly improved by using a mixture containing equal parts of wood flour and milled, dried soap powder. The wood flour, in addition to preventing caking, acts as a mild scrubber and provides an alternative surface to which the oil may become attached. The other cleansing agents examined had the defect that rinsing from the skin was difficult. Barrier creams were examined, but none gave satisfactory protection of the skin. The excessive removal of fat from the skin is discussed, and a method of investigating this problem is described.

Spontaneous Rupture of Urinary Bladder.—Taylor reports the case of a miner, aged 49, who had sustained a severe compression fracture of the first lumbar vertebra. Complete retention of urine was treated by an indwelling catheter and lavage of the bladder twice daily. After about seven weeks he had an automatic bladder and his progress was satisfactory, but about four weeks later he complained of sudden severe abdominal pain in the hypogastric region, and vomited several times. On the basis of a provisional diagnosis of a perforated stercoral ulcer immediate laparotomy was advised. At operation, which was performed four and one-half hours after the sudden abdominal pain, inspection of the bladder revealed a small hole, of about the size of the lead in a lead pencil, surrounded by a dense area of induration. Since excision and resuturing were out of the question, the sigmoid colon was pulled down into the pelvis, and an appendix epiploica sutured over the perforation, and the sigmoid colon sutured over this to the bladder wall. The patient progressed favorably and again had an automatic bladder. In view of the small number of recorded cases, the mortality rate is difficult to assess; in cases in which the operation is within twenty-four hours after rupture, the mortality rate is usually given at 11 per cent; but, if after twenty-four hours, this figure rises to 55 per cent.

Streptomycin Treatment of Pulmonary Tuberculosis.—The investigation presented by Marshall and others was planned and directed by the Streptomycin in Tuberculosis Trials Committee of the British Medical Research Council. The 107 patients reviewed in this paper had acute progressive bilateral pulmonary tuberculosis unsuitable for collapse or any other type of treatment except rest in bed. Bed rest was the treatment given to 52 of them, while 55 patients were treated with bed rest plus streptomycin. Patients were assigned to one or the other group by random selection, and only after acceptance as suitable for the trial. The period of observation for each patient was six months. The patients treated with streptomycin were given daily 2 Gm. of streptomycin, which was administered in four intramuscular injections at intervals of six hours. There were no toxic effects that required interruption of treatment, but vestibular disturbances were common. At the end of six months 7 per cent of the patients treated with streptomycin and 27 per cent of those who were treated only by rest in bed had died. Roentgenologic examination revealed considerable improvement in 51 per cent of those treated with streptomycin and in only 8 per cent of those not so treated; for slight to moderate improvement the respective figures were 18 and 25 per cent. Apart from those who died, the percentages for deterioration were 18 and 34, respectively, for the streptomycin and control cases. Improvement in the patients treated with streptomycin was greatest during the first three months; after that many began to deteriorate. In most cases resistance to streptomycin emerged in the second month of treatment. It seems probable that resistance to streptomycin is responsible for much of the deterioration seen in patients treated with streptomycin after first improvement.

Ethinyl Estradiol.—According to Jeffcoate and his associates ethinyl estradiol is an orally active estrogen first prepared by Inhoffen and Hohlweg in 1938. It is a derivative of alpha estradiol, the chemical structure of the two substances being similar. The authors decided to undertake a clinical trial of this substance mainly to assess its potency. Inhibition or suppression of lactation was chosen as the test object, as it seemed preferable to the relief of climacteric manifestations, where the interplay of psychogenic factors makes the assessment of results difficult. An attempt was made to compare the potency of ethinyl estradiol and diethylstilbestrol, both being administered orally. The results obtained in 66 women show that ethinyl estradiol is most efficient in preventing activity of the breasts. A total dose of 0.75 to 1.3 mg. spread over seven days gave good results in 21 out of 22 cases. When the total dose was reduced to 0.55 mg. the results were less satisfactory but rather better than those obtained with 35 mg. of diethylstilbestrol. Since it takes 40 to 50 mg. of diethylstilbestrol to produce good results in a high proportion of cases, it is reckoned that ethinyl estradiol is at least fifty times more active than diethylstilbestrol for the purpose of suppressing lactation. There is evidence that it is equally potent in producing other estrogenic effects; thus when it comes into general use there will be need to be caution with dosage, for otherwise ill effects such as menstrual disturbances, endometrial hyperplasia and postmenopausal bleeding, as well as toxic reactions such as nausea and vomiting, may frequently result.

Sympathectomy in Ménière's Syndrome.—Passe and Seymour say that in 12 patients with Ménière's syndrome, in whom conservative treatment had failed, Passe performed stellectomy and division of the preganglionic fibers of the first and second thoracic nerves. In 2 cases the vertebral artery was stripped, while in 4 cases it was either ligated or divided after the adventitious coat had been removed. The vertigo attributable to the pertaining ear has been completely relieved in all except 1 of the cases. Whether the recurrence of vertigo in this case was due to hypersensitivity to epinephrine or epinephrine-like bodies following excision of the ganglion (for the patient was hard at work again and under considerable mental strain), or whether some sympathetic fibers to the ear may also originate on the opposite side to a greater or lesser extent in individual cases, is not known, but the fact that there has been improvement on the administration of ergotamine would suggest that the former view is the more likely of the two, in which case division of the preganglionic fibers together with stripping and ligation or division of the vertebral artery would be the operation of choice. This has now been done in more recent cases with the same beneficial effect on the vertigo, added to which it has the advantage of avoiding Horner's syndrome. The result on the tinnitus is apparently unpredictable, though on the whole it was reduced—in 3 cases it was completely relieved. The relief seems to be more pronounced with the pulsating type of tinnitus than with the continuous variety. Each patient suffered from concomitant nerve deafness, and in all except the two most recent cases there has been improvement of hearing by both air and bone conduction. If the nerve deafness is very severe it is beyond relief.

Breast Hypertrophy and Pregnancy.—During the last five years Bankoff performed plastic reduction of hypertrophied breasts in 6 women. Four presented histories of recurrent abortion between the third and fourth month of pregnancy. All 4 patients had been under the constant supervision of a gynecologist and had undergone all necessary precautionary treatment, particularly avoiding all mental and physical strain. In spite of this, uterine contractions and hemorrhage invariably occurred after the third month of pregnancy, resulting in abortion. The 2 other women were sterile. Both had been married five years; 1 reported an occasional delay in her menstrual periods, followed by an excessive loss of blood, which pointed to a glandular disturbance if not to an early abortion. The surprising results of surgical intervention were that each patient became pregnant after the plastic reduction of the mammary glands. Five completed normal pregnancy. The last, on whom the operation was performed six months ago, is now in the fourth month of pregnancy, and there are no signs of threatening abortion. The author believes that the most feasible explanation of the connection between hypertrophy of the breasts and habitual abortion and sterility is the action of the mammary gland hormones on the pregnant uterus. It would seem that an enormous breast produces an abnormal quantity of hormone, which by the fourth month reaches saturation, thus stimulating the fibers of the myometrium and causing them to contract. This hormonal saturation in the patient with normal breasts is reached only in the ninth month of pregnancy. Further research is needed on this problem.

Infection Through Soaked Dressings.—Colebrook investigated the possibility that wound pathogens can readily grow through an intact dressing when it becomes saturated with exudates. A model wound was constructed and covered with the usual bandages. After repeated instillation of sterile serous fluid into the wound till the outer bandage was just moist, Pseudomonas pyocyanea or other wound pathogens were brought into contact with the outer bandage and the whole was incubated. Motile organisms such as Ps. pyocyanea and Proteus invariably passed through to the "wound" within a few hours; hemolytic streptococci and staphylococci passed through a little more slowly. It is suggested that some of the hospital cross infections of burns and scalds, which frequently weep copiously during the first few days, and probably also of other open wounds whose dressings become soaked, may arise in this way. A sheet of cellophane inserted in the dressing prevents the ingrowth of organisms, but is not the ideal barrier. A flexible and strong plastic film which is pervious to water vapor but impervious to bacteria is under trial.

Thromboangiitis Obliterans.—In a review of cases of thromboangiitis obliterans Kinmonth was able to trace 77 patients in whom the diagnosis was confirmed and of whom records were complete; 8 patients could not be traced. Thromboangiitis obliterans, or Buerger's disease, is an obliterating disease of the arteries and veins, usually affecting segments of vessels in the extremities. It has been suggested that Buerger's disease can burn itself out completely, but, since it is known that it can manifest itself afresh after many years, it seems doubtful whether it can ever be said to be completely cured. The cases fell into three groups according to the initial site of the disease, for it sometimes started in large vessels, sometimes in the small vessels and sometimes in both simultaneously. The main criterion of differentiation was the presence or absence of the popliteal pulse. Prognosis varied in the three groups as regards alleviation of symptoms by sympathectomy and survival of the limb. The author found that the best results are to be expected when the smaller vessels are affected—i. e., when the popliteal pulse is palpable. Improvement was not observed in the mixed type. In some early cases of unilateral Buerger's disease bilateral sympathectomy was performed. In several of these the disease subsequently appeared in what had been the sound limb. Hence "prophylactic" sympathectomy did not give complete protection, though it possibly delayed the onset of symptoms.

Parpanit® in Parkinsonism.—Dunham and Edwards say that parpanit® (diethylaminoethyl-1-phenylcyclopentane-1-carboxylate hydrochloride) is chemically closely related to the antispasmodics such as meperidine. In all, 25 patients with parkinsonism were carefully observed. Postencephalitic parkinsonism and paralysis agitans were about equally represented. All the patients had been receiving solanaceous drugs for more than a year. The results of this investigation have confirmed the usefulness of parpanit® in parkinsonism. No striking differences in therapeutic activity were seen on replacing solanaceous drugs by parpanit.® Sometimes one drug, sometimes the other, seemed more beneficial. Where parpanit® was effective it was equally so whether it was added to or took the place of solanaceous drugs; when combined medication was being given, withdrawal of either produced only minor effects. The side effects of parpanit® were similar to those of the solanaceous drugs, but their relative frequency and intensity were different. Thus, whereas giddiness, a sensation of weakness, dryness of the mouth and blurring of vision developed with both, the first two predominated with parpanit® and the last two with solanaceous medication. Preference for one or the other treatment may be determined by the nature of the side effects.

Recurrence of Duodenal Ulcer After Vagotomy.—Rob reports the case of a man, aged 40, who by the standards of the insulin test had an adequate resection of the vagal nerve supply to his stomach, and no evidence of its regeneration. His ulcer symptoms have recurred after six months. The insulin test performed after the recurrence of symptoms produced no free hydrochloric acid and only a small amount of combined acid. At St. Thomas's Hospital vagotomy has been performed on 37 patients for peptic ulcer. The early results in 5 patients with secondary ulceration following gastrectomy or gastroenterostomy have been very good. In the other 32 patients with duodenal ulcer numerous initial complications have been noted, including temporary severe dysphagia, persistent diarrhea and eructation of foul gas, but in no other patients have the ulcer symptoms recurred, though in 4 the operation was by the standard of the insulin test incomplete.

Acute Porphyria.—Little and Palmer present the case of a woman, aged 32, who ten years previously had begun to have pains in the upper part of the abdomen and the loins. In 1942 an exploratory laparotomy was undertaken, adhesiolysis and removal of an ovarian cyst being performed. This procedure did not entirely relieve the symptoms. During the last five years she noticed a gradually increasing lassitude, and she began to suffer from pain in the upper lumbar region and in both groins. She became constipated. During her first pregnancy, after six years of marriage, all her pains increased and she vomited a great deal. Following the birth of her child she noticed that the attacks of pain began to be associated with vomiting, this state of affairs continuing until December, 1947, when all her symptoms suddenly became worse and she was admitted to hospital. Laparotomy was performed on the diagnosis of an intestinal obstruction. Some coils of distended small intestine were found, some adhesions were divided and a mass in the right broad ligament was observed and removed. This mass proved on subsequent examination to consist of a portion of ovarian tissue containing a follicular cyst, and fallopian tube. During the next four weeks she continued to complain of severe pain in her back and the upper part of the abdomen and her demeanor was characterized by tearful episodes and mental changes of a regressive character. Later she was admitted to a medical unit, where her condition steadily deteriorated and where a diagnosis of acute porphyria was made after porphobilinogen had been detected in the urine. As soon as the diagnosis had been established the family history was investigated; it appears reasonably certain that 2 cousins have suffered from a similar condition. Thus the hereditary nature of porphyria seems to be established. Notes on another case of porphyria are presented. The clinical history of the first patient suggests the possibility that her last illness may not have been the first porphyric episode, and the long prodromal period of lassitude with abdominal pain for ten years is of interest. Many cases reported in the literature have been diagnosed as acute abdominal crises or as hysteria. The critical urinary picture is apt to be missed if the nursing staff discard the daily urine specimens, as the pink color does not develop immediately but is most evident after forty-eight hours.

Adhesive Tape Treatment of Leg Ulcer.—Gilje says that his chief object in advocating a revival of taping is that this procedure, as used at present, has yielded results superior to those of other types of treatment; it has proved beneficial in cases in which all other methods had failed. Favorable results largely depend on careful attention to certain technical details. Before taping is started the ulcer should be fairly clean, and for this reason it is advisable to precede taping by the use of wet dressings or dusting with boric acid, sulfathiazole or penicillin. In many instances taping can be commenced with benefit to the patient as soon as a portion of the ulcer is clean, the tape in those cases being affixed to the clean marginal zone, and wet dressings or dusting powders being continued in the remaining part of the ulcer. Strips are affixed with slight pressure to the skin on one side of the ulcer, placed immediately on the denuded surface and attached on the opposite side, the ulcer being somewhat contracted in this manipulation. The compression is most important when dealing with ambulant patients, where as a rule edema will be present. The quality of the tape is important; a good adhesive spread on tightly woven, strong cloth will produce the best results. The strips are then covered with a dry dressing. The tape may be changed every other or third day, according to the amount of exudation and the condition of the adjacent skin. If the discharge is considerable, there is no objection to changing the gauze dressing daily. Taping stimulates the formation of delicately grained, firm granulations. Excellent effects have been produced with this simple method.

*Chrysotherapy and Its "Toxic" Reactions in Rheumatoid Arthritis. G. Edström.—p. 571.

Chrysotherapy in Rheumatoid Arthritis.—Edström determined the gold level in the plasma and urine of 33 patients with rheumatoid arthritis who were treated with gold salts causing "toxic" reactions in 8 of the patients. Six presented dermatitis, 1 had gastrointestinal symptoms and 1 transient albuminuria. No parallelism could be demonstrated between gold concentrations in the plasma and urine during gold therapy and these untoward reactions. There was no statistically significant difference between the patients with and without "toxic" reactions. It is suggested that the reactions may be manifestations of hypersensitiveness of the organism to gold rather than of real toxic origin. Consequently, these reactions cannot be avoided. The reactions may occur after administration of small doses of gold, although they are usually less severe and of shorter duration than after the administration of large doses. A well balanced high vitamin diet is of importance for avoiding a high percentage of such reactions. Five patients with severe reactions to gold therapy were treated with BAL (2,3-dimercaptopropanol), 1.7 cc. (2.5 mg. per kilogram of body weight in 10 per cent solution in peanut oil, containing 20 per cent benzylbenzoate) every fourth hour, seven times by intramuscular route. These injections were followed by one to two injections daily for six to nine days. Results were satisfactory. The intramuscular injections of BAL were associated with local pain and infiltrations. No other symptoms of toxicity of BAL were observed. This treatment deserves further trial.

Systematized Nervous Diseases and Problems of Heredity (Concluded). L. van Bogaert.—p. 339.

*Surgical Treatment of Epilepsy with Focal Symptomatology. Critical Study of Results and Indications for Operation. L. Schwarz.—p. 380.

Surgical Treatment of Epilepsy.—Schwarz reports 25 cases of jacksonian epilepsy in 12 patients between the ages of 6 and 26 with encephalopathies of childhood, and in 13 patients between the ages of 21 and 48 who sustained trauma of the head, the majority of them being victims of World War II. These 25 patients were operated on in Paris by the neurosurgeon David. Four of the 12 juvenile patients made a complete recovery, 4 were improved and 4 were failures. In the adult group 4 made a complete recovery, 1 a near recovery, 5 were improved, there was 1 operative death and 1 nonoperative death, and 1 was a failure. Surgical intervention therefore was effective in 11 of the 25 patients, while partial or total failure resulted in 14. Effective surgical intervention was not limited to the motor region of the cerebral cortex but involved the precentral convolutions in 3 patients, the ascending parietal convolutions in 3 other patients, the area 8 in 1 patient, the posterior parietal region in 2 and the occipital zone in 1. At present the pathogenic basis for the surgical treatment of jacksonian epilepsy is not sufficient for envisaging a radical cure in all cases. Cases, the cause of which could be traced to childhood, and the "cryptogenic" cases offer a less favorable prognosis for surgical intervention than the post-traumatic cases with corticomeningeal cicatrization. A thorough clinical examination supported by a complete history may be sufficient for the right selection of patients to be operated on. The consideration of the latent period is of no value in patients with attacks whose cause can be traced back to childhood. The total length of time during which the patient had epileptic attacks is of great prognostic value, since surgical treatment seems to offer less chance for patients who have had attacks for more than two to three years. Irreversible character of the condition is indicated by increase in frequency of the attacks and by the tendency to repeated loss of consciousness. The coexistent deficiency of various cortical functions suggests a generalized involvement of the brain and is a serious contraindication to surgical intervention.

*Syndrome of Bronchial Obstruction with Passage of Air. R. F. Vaccarezza and A. Soubrié.—p. 5.

*Experimental Stenosis of Pulmonary Artery. V. J. A. Alberti, O. C. Croxatto and A. Lanari.—p. 24.

Bronchial Obstruction with Circulation of Air.—Vaccarezza and Soubrié report 9 cases of a special type of bronchial obstruction in patients with pulmonary or bronchial tuberculosis. It is characterized by circulation of air through the stenosed segment of the large bronchi. Bronchospirometry showed that the functional value of the lung was insignificant or nil. Respiration was abolished in the corresponding pulmonary segment notwithstanding the fact that air was present in the lung parenchyma of that segment, as shown by roentgenograms. Obstruction of this type hinders the passage of air and stops aeration of the blood in the corresponding pulmonary segment, whereas it allows passage of air in sufficient amount to keep the lung expanded. Cases of atelectasis from bronchial obstruction with clear spots in the consolidated zone of the pulmonary parenchyma are due to the same mechanism as that which causes the syndrome described.

Experimental Stenosis of Pulmonary Artery. — The experiments were performed on dogs. The stem of the pulmonary artery was constricted to 50 per cent of its lumen and the experiment repeated by reoperation. The tension of the pulmonary circulation proximal to the stenosed segment of the pulmonary artery increased greatly, 27.36 mm. in systolic pressure immediately after ligation and a further increase of 32.28 mm. in the reoperation. Hypertension produced considerable dilatation of the right ventricle. There is an evident relationship between the degree of hypertension, the diameter of the myocardial fibers, the weight of the heart and the time of survival of the animal.

Study of Results Obtained in Treatment of Fractures of Lower End of Radius in Insured Persons in Finland. O. Valtonen.—p. 287.

Treatment of Varicose Veins.—Tuomikoski treated 340 patients, 268 women (78.8 per cent) and 72 men (21.2 per cent), between the ages of 18 and 78 years, who had varicose veins, by ligation and injection in both central and peripheral directions. The great saphenous vein was ligated 5 to 10 cm. below the groin, and 1 or 2 cc. of 20 per cent sodium chloride solution was injected slowly in the central and 5 to 10 cc. quickly in the peripheral direction. The lesser saphenous vein was ligated 2 or 3 cm. below the knee joint, and 0.5 or 1 cc. of the solution injected in the central and 3 to 5 cc. in the peripheral direction. Postoperative injections were made in the beginning with sodium chloride or quinine-urethane, later exclusively with 10 per cent sodium morrhuate into empty veins. In 38 patients with indolent ulcer of the leg a supporting bandage was also used. Immediately after the injection pain was often felt in the limb down the foot, sometimes fairly severe, but subsiding in a few minutes. The patients were allowed to walk home and to resume their regular work. On these 340 patients a total of 494 ligations of the saphenous veins, 478 of the great and 16 of the lesser saphenous veins, were performed. In 57 per cent of the cases the dilatations were obstructed after ligation without postoperative injections. An average of 2.4 supplementary injections were required in 43 per cent of the cases. Periphlebitis occurred thirteen times (2.6 per cent), mild wound infection twice (0.4 per cent) and postoperative hemorrhage once (0.2 per cent). Necrosis of the skin occurred twice in connection with one postoperative injection of sodium chloride and one of quinine-urethane, but did not after injection of sodium morrhuate. There was no certain case of embolism. Follow-up could be done on 133 patients on whom a total of 204 ligations of the great saphenous vein and 6 of the lesser saphenous vein were performed. No signs of recurrence were noted in 90 limbs (43 per cent) while 120 limbs (57 per cent) did show recurrence. In 96 cases the great saphenous vein was entirely or partly recanalized and in 81 of these a deep communicating vein was observed to have incompetent valves. The immediate results obtained by this method are equally good and the end results are nearly as good as those obtained by high ligation and retrograde injection. The risk of embolism is probably smaller than in any other operative procedure. In all cases of incompetence of deep anastomoses the deep communicating veins have to be ligated as well.

*Remarks on Prognosis of Simple Persistent Patency of Ductus Arteriosus Based on 54 Patients not Operated on. J. J. Welti and G. Koerperich.—p. 428.

Persistent Patency of Ductus Arteriosus.—Welti and Koerperich report 54 patients, 17 men and 37 women, with persistent patency of ductus arteriosus. Thirteen were not heard from, 7 died and 34 have been followed up, 15 for less than five years, 8 for five to ten years, 5 for ten to fifteen years and 6 for fifteen to twenty years. Four of the 34 patients were aged less than 10 years, 7 were between the ages of 10 and 20, 10 between the ages of 20 and 30, 6 between the ages of 30 and 40, 4 between the ages of 40 and 50 and 3 aged 53. These 34 patients are leading a life near to normal, their hearts do not seem to become enlarged from one examination to the next, functional symptoms if present are mild and have not become aggravated with increasing age. Pregnancies are possible at least in a limited number. Of 14 women in the child bearing age period, 3 had 3, 2 had 2, and 4 had 1 child. The study of the 7 fatal cases showed that an accident may occur suddenly and death may result rapidly if not immediately. Infectious endarteritis seems to result less frequently in France than in the United States and England. Sixteen of the 34 patients have been studied in detail, and their condition apparently did not justify surgical intervention. Two of them, however, died suddenly. Although the statistics as a whole are less unfavorable the authors believe that surgical intervention for patent ductus arteriosus may have been omitted in France too often. Hesitation may be permissible but seems less warranted in the presence of definite dyspnea or decisive handicap in the general development of a young person.

*Vulvovaginitis, a Frequent Complication of Measles. M. Schachter. —p. 533.

Vulvovaginitis with Abscess in Measles.—Schachter says that this condition is rare. He reports a case of acute vulvovaginitis with an abscess complicating benign measles. The condition is very painful. Treatment consisted of local warm compresses, irrigation with a very mild permanganated tepid water and administration of a sulfonamide drug in daily doses of 3 Gm., for two consecutive days. The abscess opened spontaneously and the lesion was healed in forty-eight hours.

*Rare Finding During Dacryocystitis. A. Alcala Lopez.—p. 1048.

Rare Finding During Dacryocystitis.—In a man 26 years of age a small tumor had developed at the age of 11 in the area of the right lacrimal duct. The tumor had disappeared and left as a sequel chronic suppurative dacryocystitis with a fistula. During a successful operation, which consisted of removal of the lacrimal sac, a canine tooth was found in the place previously occupied by the lacrimal sac. The tooth, the tissues about it and the fistula were removed. The author believes that the fistula corresponded to a dermoid cyst which contained the tooth. No similar finding in the lacrimal sac was previously reported in the literature.

Experience with Vitamin D_2 in Lupus. R. Lenggenhager.—p. 40.
*Etiology of Woodcutter's Eczema. F. Tenchio.—p. 72.

Keratosis Follicularis "Epidemica" (Basel Disease).—Schenker reports that in the fall of 1946 keratosis follicularis was observed in "epidemic" form in many patients in insane asylums in Switzerland. It developed in patients who were occupied in separating the tinfoil used in packing butter, cheese, cigarets, etc., from the attached paper, for the purpose of salvaging the tinfoil. Since February 1946, a new mixture of wax and paraffin with some additions had been used as paste, and the question now arose whether the cause of the disorder might not be contained in this mixture. This assumption is supported by the fact that in the factory in which the tinfoil was produced, the same disorder appeared in the workers who tended the machine which attached the paper to the tinfoil by means of the mixture and also in a worker who tended the machine mixing the paraffin.

Woodcutter's Eczema.—The eczema of lumber workers, described by Tenchio, is usually localized in the waistline which the workmen are in the habit of girding with a scarf or sash. It is also seen round the neck of persons who transport wood on their shoulder. The fact that the eczema never attacks persons working on young trees, but only those felling older trees, gave rise to the theory that a lichen on the old tree trunks, viz., the Parmelia caperata, might possibly be the cause of the eruption. Experiments made with the lichen itself and with an extract prepared from it proved the correctness of this supposition. But the lichen only induces the eczema when accompanied by severe sweating and exposure to sunlight.

*Primary Lymphosarcoma of Stomach and Its Relations to Peptic Ulcer. H. Kreitner.—p. 423.

Lymphosarcoma of Stomach and Peptic Ulcer.—Kreitner says that in the course of two years 5 lymphosarcomas of the stomach were treated at a Vienna clinic. A correct diagnosis was never made before the operation. Three times a peptic ulcer was suspected and in the other 2 cases it was assumed that malignant degeneration had taken place in a peptic ulcer. The true nature of the lesion was revealed only by microscopic study. In 4 of the patients two thirds of the stomach was resected and in one case the antrum was resected. In this instance the primary sarcoma was not removed and this patient died six months later with metastases in the liver and kidney. The other patients are still alive; however, only two years have elapsed since operation in the earliest case. The author points out that many observers have assumed the possibility of the development of lymphosarcoma from a peptic ulcer, although this has not been definitely demonstrated, and there are some who reject such a pathogenesis. Three of the 5 patients observed by the author had had ulcer symptoms for years before the lymphosarcoma was discovered, and 1 had been unsuccessfully treated for a duodenal ulcer. The 5 cases of lymphosarcoma seen at the author's clinic were detected among 69 gastric carcinomas and 350 peptic ulcers. The average age of the 5 patients was 53 years. The site of predilection seems to be the prepyloric and the antral region. Eighteen months is the average survival time when the lymphosarcoma remains untreated; with surgical treatment the prognosis is about the same as in gastric carcinoma, but the radio sensitivity of lymphosarcoma is better than that of carcinoma.

*Herpes Zoster in Spondylarthrosis Deformans and in Hernia of the Nucleus Pulposus. A. M. L. de Haas.—p. 3195.

Herpes Zoster in Spondylarthrosis Deformans and in Hernia of Nucleus Pulposus.—According to de Haas herpes zoster is chiefly a disease of the peripheral sensory neuron. This neuron may became predisposed to an attack by the zoster virus when it has become impaired by another process. Such impairment may be caused by various disorders of the spinal column. The author reports 2 cases of severe spondylarthrosis and 1 of hernia of the nucleus pulposus. In these cases herpes zoster developed in the areas of the peripheral sensory neurons that correspond to levels of the spondylarthroses and the disk hernia, respectively.

Air Embolism After Insufflation of Fallopian Tube. K. Kulseng-Hanssen.—p. 1783.

Effect of Desoxycorticosterone Acetate and Sodium Chloride in Orthostatic Anemia and Postural Hypotension.—Luft and Sjögren report that in 2 cases of postural hypotension treament with *20* mg. desoxycorticosterone acetate and 10 Gm. sodium chloride daily resulted in a moderate rise in systolic and diastolic pressure; the patients could stand upright and walk about relatively well and return to a fairly normal way of life. In the 2 cases of orthostatic anemia similarly treated the abnormal orthostatic changes disappeared and the patients were subjectively well and again able to lead a normal life. Continued supply of desoxycoricosterone acetate was furnished by tablet implantation (5 tablets of 100 mg. each), administration of the hormone in crystalline suspension (injection of 50 mg. every other week) or by tablets orally (5 mg. daily).

Leukemia and Phosphatase.—Dalgaard estimated the serum phosphate in 25 cases of leukemia by the Buch and Buch method mainly in relation to variations in the leukocyte count on roentgen treatment. In patients with lymphatic leukemia, aleukemic myelogenous leukemia and plasmacellular leukemia the values were normal before and after roentgen treatment. In chronic myeloid leukemia there was usually, coincident with the reduction in the leukocyte count, a distinct rise in serum phosphatase after roentgen treatment; in 2 cases, however, the phosphatase reaction was negative. The reduction in the number of mature leukocytes is believed to be decisive for the phosphatase reaction. Histochemical investigations according to Gomori show abundant phosphatase in these cells. The improvement reported in the literature in leukemia patients treated with radioactive phosphorus seems to occur predominantly in patients with chronic myeloid leukemia, and it is suggested that the treatment should be applied in selected patients shown to be phosphatase positive.

Additional Cases of Nephropathia Epidemica.—Myhrman reports 8 new cases of an infectious disease of unknown origin observed in Northern Sweden and previously described by him and others. It is marked by acute onset with fever, abdominal pain and transient nephrotic syndrome.

Cancer of Breast in Zurich. H. R. Schinz and C. Botsztejn.—p. 91.
*Mammary Cancer in Man (Question of Relation Between Mammary Cancer and Sex Hormones). C. Botsztejn and H. R. Schinz.—p. 110.

Mammary Cancer in Man.—Reviewing the present status of knowledge on the relationship between sex hormones and mammary cancer, Botsztejn and Schinz point out that animal experiments on mice from breast carcinoma strains indicate that estrogenic hormones favor the development of mammary cancer whereas androgenic hormones are antagonistic to it. The authors cite clinical observations on this problem and review observations on 11 breast cancers that were observed in men during a period when 1,027 women with breast cancer were treated. Thus the incidence of male to female mammary cancer is about 1 : 100. As regards the microscopic structure and the clinical course, carcinoma of the male breast does not differ from carcinoma of the female breast. Apparently gynecomastia is the factor that predisposes to the development of cancer of the breast in men. The treatment of gynecomastia with male hormone may act prophylactically against carcinoma. After cancer has developed, treatment with sex hormones is only an adjuvant to other treatments. Surgical treatment or radium therapy must not be omitted. Castration, roentgen sterilization *and estrogenic hormones are contraindicated in men; their value* in women is not proved. A trial with male hormones is justified as a palliative measure in cancer of the breast in both sexes.

*Experiences with Epidemic of Poliomyelitis in 1947. E. Lorenz.—p. 677.
Surgical Removal of Blood from the Filled Operative Cavity After Pneumolysis. K. Janauschek.—p. 680.
Contribution to Differential Diagnosis of Sprue. R. P. Koenigstein. —*p. 681.*
General Problems of Irradiation Therapy. K. Weiss.—p. 683.

Epidemic of Poliomyelitis.—Lorenz reports 168 children with acute anterior poliomyelitis who were admitted to the pediatric clinic and the ward for infectious diseases in Graz, Styria, in 1947. Contrary to expectation, the highest incidence was observed among children aged 7 and 8, rather than in infants, and the incidence decreased rapidly in children between the ages of 12 and 14. Only 45 per cent of the patients were suckling babies and infants, while 55 per cent were between the ages of 6 and 14 years. There were only 5 deaths, 4 of them in children of preschool age. This mortality rate of only 3 per cent as compared to that of 8 to 10 per cent in epidemics of previous years may be explained by the clinical aspect of the cases reported. Fifty-four—i. e., one third of the cases—were of the meningeal, aparalytic type, with signs of severe irritation of the spinal cord and decisive changes in the cerebrospinal fluid; 93 cases (55.4 per cent) were of spinal paralytic type and only 20 cases (12 per cent) were of cerebral paralytic type. There was only 1 case of spinal ataxia. On admission only 14 of the 168 patients (8.3 per cent), 10 of spinal paralytic and 3 of cerebral paralytic type, had a normal cerebrospinal fluid; 128 patients, 44 of them of the meningeal type, 71 of the spinal paralytic and 13 of the cerebral paralytic type, had pleocytosis and normal albumin level; 20 patients had pleocytosis with elevated albumin level; only 6 patients presented Guillain-Barré's albuminocytologic dissociation. After three or four weeks' duration of the disease the cerebrospinal fluid was restored to normal in only 96 patients, 15 had pleocytosis, 8 pleocytosis and increased albumin content, but 45 presented albuminocytologic dissociation, which shows that in poliomyelitis increase in lymphocytes does not always parallel that in albumin. Recurrent increase in lymphocytes but little increase in albumin was observed in 8 patients between the ages of 4 months and 13 years, in the third week of the disease after the cerebrospinal fluid had been improved but not yet restored to normal. There was a long period of convalescence in all patients, and the cerebrospinal fluid did not become normal for some months.

Book Notices

Virus Diseases of Man. By C. E. van Rooyen, M.D., D.Sc., M.R.C.P., Research Member and Professor of Virus Infections, Connaught Medical Research Laboratories and School of Hygiene, University of Toronto, Toronto, and A. J. Rhodes, M.D., F.R.C.P., Research Associate and Associate Professor of Virus Infections, Connaught Medical Research Laboratories and School of Hygiene, University of Toronto. Cloth. Price, $22.50. Pp. 1202, with 43 illustrations. Thomas Nelson & Sons, 385 Madison Ave., New York 17, 1948.

Since the first edition of this outstanding monograph covering the field of human and animal virus infections appeared in 1940, many advances have been made in this field and at least twenty new viruses have been discovered. That both the fundamental and applied aspects of virus research have made rapid strides is fully reflected in the extensive revisions and expansions of the text. The authors have critically reviewed and appraised with due regard to respective value every publication on virus infections in the ten year period between 1938 and 1948. For an actively developing field with its ramified ecologic implications this revision was indeed urgently needed. They have added 270 pages to the 1940 edition and vigorously condensed and eliminated unessentials. In so doing, they dropped the chapter by T. J. Mackie which reviewed, in a readable form, the historical evolution of the knowledge of the viruses of man and animals. This minor omission is well counterbalanced by the inclusion of a store of newer information on some statistical methods in virus studies, serologic technic, the fertile egg in the study of viruses and other phases. Each chapter of the eighty-nine which deal with the various aspects of the respective virus infections is admirably balanced and contains concise data concerning the clinical aspects with reference to diagnostic aids, immunoprophylaxis and specific therapy and antibiotics if available. It satisfies the needs of the teacher, clinician and laboratory worker. For example, the chapters on the variola-vaccinia virus carries in 25 pages nearly 1,500 references, and the review on poliomyelitis required a bibliography of 1,000 references on 24 pages. A complete index and excellent printing of the text with well chosen illustrations and readily readable tabulations and charts recommend this work as the most complete reference book on the virus infections of man.

A Handbook for the Diagnosis of Cancer of the Uterus by the Use of Vaginal Smears. By Olive Gates, M.D., Pathologist, Massachusetts State Tumor Diagnosis Service, Boston, and Shields Warren, M.D., Assistant Professor of Pathology, Harvard Medical School, Boston. With a foreword by George N. Papanicolaou, M.D., Ph.D., Associate Professor, Department of Anatomy, Cornell University Medical College and New York Hospital, New York. Paper. Price, $4. Pp. 182, with 50 plates. Harvard University Press, Cambridge 38; Oxford University Press, Amen House, Warwick Sq., London, E.C. 4, 1947.

This book, devoted to the study of vaginal, cervical and endometrial cells and their malignant components, is a valuable one. The careful and well judged arguments, pro and con, for the value of the smear are fair and carefully considered. The authors admit freely their difficulties with certain types of cells and the necessity of prolonged study and observation before qualifying as an expert in this method of diagnosis. They have carefully set forth the methods best suited for collecting, preserving and staining the specimens so that any one interested in the problem can soon learn how to obtain and stain satisfactory specimens. Gates and Warren discuss the morphology and normal histology in chapters that are easy to read and clearly written. The descriptions of malignant cells and their characteristics are well done. The whole text is honest, clear, concise and as important a contribution as has been made by any one in the study of this new method of diagnosis. The photomicrographs that illustrate the normal and malignant cells are beautiful and characteristic of the work of their laboratories. It is the reviewer's belief that the grouping of the photomicrographs might have been done better for the neophyte and that perhaps the doubtful cells pictured might have been left out all together. The illustrations with the easily understood captions are extremely satisfactory and probably will mean more to an interested pathologist than any group of photomicrographs as yet published. This book is important and should be a must for all laboratories interested in the cytology of normal and malignant cells.

Gynaecological Histology. By Josephine Barnes, M.A., D.M., M.R.C.P., Assistant, Obstetric Unit, University College Hospital, London. Cloth. Price, 30s. Pp. 242, with 162 illustrations. Harvey & Blythe, Ltd., 6 Hanover Square, London, W. 1, 1948.

This small book was written with the object of providing a simple guide to the histology of the normal and abnormal tissues encountered in gynecologic practice. All but one of the illustrations consist of photomicrographs from actual slides. The author hopes that the majority of the readers will have access to slides so they can compare the appearance as seen under the microscope of the tissues described and illustrated in the book.

The book contains 162 illustrations and only sufficient text material to explain the chief points in the histology of the tissues which are illustrated. The choice of material is excellent, the photographs are all that can be desired and the text is written in clear simple language. This book should prove to be most helpful to all young gynecologists and to older ones who never had training in gynecologic pathology. Certainly any one who performs gynecologic operations must possess the knowledge which this book imparts. The author and the publishers are to be congratulated on having produced an excellent. compact book on gynecologic histology.

Textbook of the Rheumatic Diseases. Edited by W. S. C. Copeman, O.B.E., M.D., F.R.C.P., Physician to the Rheumatism Department and Lecturer in the Medical School, West London Hospital, London. Cloth Price, $12.50. Pp. 612, with 351 illustrations. Williams & Wilkins Co., Mt. Royal & Guilford Aves., Baltimore 2, 1948.

Here, typical of many recent works in medicine, is a composite volume to which twenty-four noted British physicians have contributed. This is the first book exclusively devoted to rheumatic diseases developed in Great Britain. The work begins with a discussion of the nomenclature and classification of rheumatic diseases and then devotes separate chapters to all of the different forms from rheumatic fever to sciatica. Other chapters are concerned with differential diagnosis, pathology, radiology, physical therapy, orthopedics and psychiatric considerations. The classification adopted is one developed by a special committee of the Royal College of Physicians. The historical article indicates the antiquity of rheumatic disease, which was described by Hippocrates. Indeed, remnants of arthritis have been found in bodies far antedating the time of Hippocrates. The historic chapter has an excellent bibliography. Since every part of the body is concerned in rheumatic diseases, sections are devoted to the skin and to the anatomy and physiology of pain. The book is beautifully printed on good enamel stock so that the illustrations are among the best available in any work of this character. Among the most important of the discussions is the consideration of weight reduction in cases of osteoarthritis in which treatment may fail unless weight reduction is assured. The consideration of fibrositis, which is a subject of considerable controversy, is adequate; it is discussed in relation to every phase of diagnosis, pathology and treatment of the disease. Several volumes on the rheumatic diseases are available in the American literature. American readers will be especially interested in some of the differences in point of view that prevail among British writers.

Health of Workers Exposed to Sodium Fluoride at Open Hearth Furnaces. Prepared by direction of the Surgeon General by J. Walter Hough and others, Industrial Hygiene Division, Bureau of State Services. Public Health Bulletin No. 299, Federal Security Agency, Public Health Service. Paper. Price, 25 cents. Pp. 61, with 2 illustrations. Supt. of Doc., Government Printing Office, Washington 25, D. C., 1948.

This government document presents an authoritative report of a complete and exhaustive study of the subject conducted by the Industrial Hygiene Division of the U. S. Public Health Service on the request of representatives of the Republic Steel Corporation and the United Steelworkers of America, C. I. O. Numerous questions have arisen concerning the effects of sodium fluoride on health in industry, particularly in connection with its use in open-hearth operations in steel mills. Suspicion of potential health hazards inherent in its use has provoked much labor unrest. Workers have complained bitterly about its use.

Field work was conducted in four Republic Steel Corporation plants in Ohio. Medical examinations were made of 350 men, distributed as follows: One hundred and eighty-seven in two plants now using sodium fluoride, 63 in a plant where sodium fluoride formerly was used and 100 as a control group in a plant which had never used sodium fluoride. Laboratory investigations included determinations of amounts in the air of: fluorine, total fume, oxides of iron, and manganese. Roentgen diffractions were made of fume and dust. Urine samples were studied to determine their fluorine content.

The medical and dental study included a detailed occupational history and a record of past diseases, operations and injuries. Present symptoms were recorded with special emphasis on irritative effects of fume. A complete physical examination was performed with attention directed toward any evidence of lens opacity and inflammation of the mucous membranes of the eyes, nose and throat. A roentgenogram of the chest was taken of each worker as well as one of his left wrist and forearm. A clinical oral examination was made of each employee.

Concentrations of iron oxides and manganese fumes were below the accepted maximum allowable concentrations, and it is concluded that they would not constitute a significant health hazard. On a basis of physical and roentgen observations, there were no definite changes attributable to sodium fluoride. It was concluded that exposure to sodium fluoride has little or no disabling effect on the tissues and structures of the oral cavity and that sodium fluoride does not produce tissue necrosis when introduced into the oral cavity in the atmospheric concentrations reported. However, sodium fluoride, in combination with other fumes and dusts, may be a contributing factor in producing soft tissue inflammation in the mouth.

From these findings, it appears that sodium fluoride does not constitute a significant health hazard under the industrial environmental conditions of this study.

Recommendations are submitted with a view to reducing the density and irritation of smoke and fume produced in this industrial process.

Index of Treatment in Small-Animal Practice. By Hamilton Kirk, M.R.C.V.S., Official Veterinary Surgeon to Clapton Greyhound Stadium, London. Cloth. Price, $10. Pp. 773, with 154 illustrations. Williams & Wilkins Co., Mt. Royal & Guilford Aves, Baltimore 2, 1948.

The author has gathered a vast store of information on veterinary therapeutics, particularly that which pertains to the treatment of dogs and cats. This has been segregated from general discussions in current articles, has been condensed to concise form and is presented as an alphabetic, encyclopedic treatise on the alleviation of the ills of dogs and cats. The diagnosis is not a part of the text, having been discussed in a preceding volume.

Part I of the book (consisting of 146 pages) presents a systematic discussion of the several types of therapy—actinotherapy, radiant heat therapy, electrotherapy, chemotherapy, hormone therapy, vaccine and serum immunization and therapy, nonspecific vaccine therapy, vitamin therapy, the barbiturates, the antiseptics (wound, intestinal and urinary) and the anesthetics (local and general).

Part II (consisting of 479 pages) provides the body of the book, with an alphabetic, encyclopedic discussion of conditions varying from abdominal pain to yawning.

Part III (96 pages) describes the procedures for handling and restraint, administration of medicine, nursing the sick, food and feeding, disinfectants and disinfection, euthanasia and rat extermination and includes a posologic table, general information and tables, the poison acts and an addendum which presents recent information on penicillin, sulfamezathine,® (2-sulfanilamido-4,6-dimethylpyrimidine), leptospiral jaundice, eczema or pruritus, anorexia and marasmus, encephalitis and sarcoptic mange.

All this information is made available through an index of 42 pages. In one notable respect it differs from most texts printed in the United States: The discussion, the tables and the index include the proprietary remedies commonly merchandised in Great Britain along with the pharmaceutic drugs and their dosages and actions. For the person who has arrived at a diagnosis, the book presents a vast assortment of opinions and suggestions for treatment.

Methods in Medical Research. Volume I. Van R. Potter, Editor-in-Chief. Assay of Antibiotics, Henry Welch, Editor; Circulation—Blood Flow Measurement, Harold D. Green, Editor; Selected Methods in Gastroenterologic Research, A. C. Ivy, Editor; Cellular Respiration, Van R. Potter, Editor. Cloth. Price, $8. Pp. 372, with illustrations. Year Book Publishers, Inc., 304 S. Dearborn St., Chicago 4, 1948.

This volume is the first of a series, presenting descriptions and critical evaluations of methods, apparatus and step by step procedures in various fields of biologic and medical research. The present publication covers four fields: (1) assay of antibiotics, (2) circulation—blood flow measurement, (3) selected methods in gastroenterologic research and (4) cellular respiration. Each section is in charge of an associate editor, and some contain contributions and comments by particular experts on special aspects, so that altogether some fifty contributors and reviewers have added their knlowledge to this compilation.

This book and others to follow will meet a long felt need in biologic and medical laboratories, and should also be of considerable interest to physicians who wish to know the basis on which many of the facts which they use in practice have been established. The authors and publishers are to be congratulated on a useful service, well performed.

Radiotherapy and Cancer. By A. G. C. Taylor, M.R.C.S., L.R.C.P., D.R., Joan Lassetter, M.B., Ch.B., D.R., and T. K. Morgan, M.B., M.R.C.S., D.M.R. (T), Radiotherapists of the Wessex Radiotherapy Board. Boards. Price, 7s. 6d. Pp. 81. H. K. Lewis & Co., Ltd., 136 Gower St., London, W.C. 1, 1948.

This booklet of 81 pages illustrates the trend in radiotherapy in a scheme of socialized medicine. The radiation therapy is given at a specially equipped and staffed center. Briefly, the work explains the mode of action and the effects of treatment with radium and roentgen rays, how cases are selected for treatment and, in brief form, the methods employed. The authors are the radiotherapists of the Wessex Radiotherapy Board, controlling the facilities for radiotherapy and the radiotherapeutic staffs at Southampton, Bournemouth and Portsmouth. In the second part of the book they give their ideas as to how cancer should be treated. These views are generally accepted in radiotherapeutic circles. Although surgical treatment is nearly always ignored if there is no hope of cure, these patients are given the benefit of radiotherapy for palliation. In a large percentage of cases the program of treatment is dependent on whether it is decided to try to cure or to palliate or whether to leave alone.

Hematology. By Cyrus C. Sturgis, Professor of Internal Medicine, Chairman, Department of Internal Medicine, University of Michigan Medical School, Ann Arbor, Michigan. Fabrikoid. Price, $12.50. Pp. 915, with 80 illustrations. Charles C Thomas, 301-327 E. Lawrence Ave., Springfield, Illinois, 1948.

The American textbooks on hematology are continually increasing. In 1897 the only American text was that of Richard C. Cabot.

Sturgis' book is published in large readable type on heavy glossy paper. Two features make it distinctive: (1) a detailed, comprehensive approach to history and (2) a truly comprehensive review of the literature. The historical discussions are not to be found in any other similar book. Sturgis points out in his preface how the development of the historical approach leads to a better understanding of a disease condition or therapeutic maneuver and to a better fixation of the disease in memory. The references to the literature are given in full at the bottom of the page on which they are cited. They are also repeated in alphabetical order at the back of the book; altogether, about 100 pages are devoted to references.

This sound book is recommended to students and practitioners. Functional pathology is not stressed, and because of this the book not infrequently suffers. The conventional or nosologic approach is probably best for the student.

The book begins, not with a discussion of embryonic blood formation or of hematopoiesis, as is customary, but with a chapter on anemia. Although this highlights the practicality of the work, some students might carp at the rather scant attention paid to fundamental cytology and hemopoiesis.

The chapter on pernicious anemia is outstanding. That on erythroblastosis fetalis is rather sketchy. There is an excellent chapter on agranulocytosis. An 18 page chapter on sternal puncture and an 80 page chapter on blood transfusion and blood substitutes complete the book.

The colored lithographs are in general "muddy" and could be much better. The line drawings are good. The artistic merit of the big word "hematology," which occupies the entire "backbone" of the book, is to be questioned.

In summary, this new book on hematology, which emphasizes the practical, the historical and the bibliographic approach, should be of great value to the student and practitioner; the outstanding bibliography will be of value to the investigator of source material.

An Introduction to Medical Mycology. By George M. Lewis, M.D., Associate Professor of Clinical Medicine (Dermatology), Cornell University Medical School, New York, and Mary E. Hopper, M.S., Third edition. Cloth. Price, $8.50. Pp. 366, with 105 illustrations. Year Book Publishers, Inc., 304 S. Dearborn St., Chicago 4, 1948.

Many improvements have been incorporated in the third edition of this volume. There is an even greater number of the excellent illustrations than in previous editions, and the appearance of this volume has been generally streamlined. More data on the physiology of fungi have been added. Cross sensitization between penicillin and certain dermatophytes is discussed. A number of additional fungi have been included in the chapter on pathogenic fungi. The discussion of tinea of the scalp has been brought up to date on the basis of the authors' observations during the recent scalp ringworm epidemic.

In some parts of the book, such as in the chapter on otomycosis, the more recent advances in knowledge, acquired during the war, have not yet been included. Some of the debatable statements made and directions given in previous editions, including, for example, the "ritual" for prevention of tinea pedis, have been retained. However, this well recognized book is the most useful and practical volume on medical mycology, particularly for the dermatologist.

Microbiology and Pathology. By Charles F. Carter, B.S., M.D., Instructor in Pathology and Applied Microbiology, Parkland Hospital School of Nursing, Dallas, Texas. Fourth edition. Cloth. Price, $5. Pp. 845, with 241 illustrations. C. V. Mosby Company, 3207 Washington Blvd., St. Louis 3, 1948.

This edition, as were the previous editions, is designed primarily for use in training schools for nurses. For this purpose, it still retains exercises at the end of each chapter in the form of true and false questions and completion tests of sentences that apply to contents of each chapter. In bacteriology, a discussion on sulfonamide compounds and antibiotics has been added. An attempt is made to use some of the newer nomenclature and at the same time retain the old. Improved methods of immunization are discussed in a new chapter. In the section on pathology, considerable material has been revised. A chapter on defects of body development is a new feature. Good illustrations have been added, but many of the old black and white and colored could have been replaced by more modern photographs. The book is recommended especially for use in courses of bacteriology and pathology for nurses.

The Child in Health and Disease: A Textbook for Students and Practitioners of Medicine. By Clifford G. Grulee, M.D., Rush Professor of Pediatrics, University of Illinois, Chicago, and R. Cannon Eley, M.D., Associate in Pediatrics and Communicable Diseases, Harvard University Medical School, Boston. Cloth. Price, $12. Pp. 1066, with illustrations. Williams & Wilkins Co., Mt. Royal & Guilford Aves., Baltimore 2, 1948.

This new volume was begun before the recent war and was delayed in publication by the stresses of that period. When the war ended a complete revision of each of the contributions became necessary. In the introduction the editors point out that the shortage of pediatricians makes necessary much more training of general practitioners to meet the needs of practice in this field. The present volume is a collection of articles written by a great number of contributors to pediatric knowledge. The book is classified by disturbances of various systems of the body and by various types of disease. Special sections are concerned with adolescence, and there is a section on surgical pediatrics. A final chapter discusses a variety of subjects not easily classified. The book is printed on an excellent quality of paper stock with fine illustrations, charts and tables. The book is authoritative in its statements, succinct in its presentation and bound to be helpful to both specialists and general practitioners, as well as to students.

Les varices de la grossesse et leur traitement principalement par les injections sclérosantes. Par Raymond Tournay et Pierre Wallois. Paper. Price, 250 francs. Pp. 139, with 12 illustrations. L'Expansion scientifique française, 23 rue du Cherche Midi, Paris 6ᵉ, 1948.

This is a well written, concise monograph on the management of varicosities of the lower extremities, vulva, vagina, rectum and suprapubic region during pregnancy. The authors believe in a strong hereditary factor, discount the pressure of the enlarged uterus as an important causative agent, but believe in an endocrine influence on smooth muscle to explain the venous atony and back pressure during the pregnant state. They describe the clinical picture and complications illustrated with excellent, large photographs. In addition, excellent black and white drawings are used in the text. They believe in the injection treatment of varicosities, no matter where they are situated. They do not believe in preliminary ligations combined with sclerosing therapy, nor do they seem to limit their injections to cases of a valvular insufficiency of the saphenous system. The monograph may be recommended to obstetricians to stimulate their interest in this complication of pregnancy. The suggestions regarding prophylaxis, early treatment and prevention of postpartum phlebitis are sound. Their method of treatment, which does not eliminate the valvular insufficiency of the deep venous systems of the leg and pelvis from sclerosing therapy, is highly debatable.

An Introduction to Color. By Ralph M. Evans, Color Control Department Head, Eastman Kodak Company, Rochester, N. Y. Cloth. Price, $6. Pp. 340, with 304 illustrations. John Wiley & Sons, Inc., 440 Fourth Ave., New York 16; Chapman & Hall, Ltd., 37-39 Essex St., Strand, London, W. C. 2, 1948.

The author, who is head of the color control department of the Eastman Kodak Company, has written a valuable book on the physics, physiology and psychology of color. The description of the rather complex physical conditions which determine color is lucid and accurate in spite of the use of nontechnical language, and is discussed on the basis of numerous diagrams. The physiologic and psychologic factors which determine the perception of brightness and color are discussed in detail and illustrated by beautiful color plates. The work deviates greatly from previous classical texts of this field and must be considered as a valuable supplement to the physiologic literature on color vision.

Disfunciones motoras del estómago. Por el Doctor E. Arias Vallejo. Prólogo del Profesor E. Oliver Pascual. Paper. Price, 35 pesetas. Pp. 155, with 66 illustrations. Agencia Garsi Publicidad Médica, Cava Baja, 11, Madrid, 1947.

This monograph on the motor dysfunctions of the stomach is well written and contains a large amount of information, mainly obtained from the literature. However, there are many illustrations and records of observations made by Vallejo himself. He makes some interesting observations on the slowing of gastric emptying which occurs with some inflammation of the small bowel.

Estudo da pericardite experimental. Por Eduardo Coelho, Artur de Oliveira, Leonel Cabral e Manuel Prates. Paper. Pp. 77, with illustrations. Lisbon, 1946.

This monograph presents the authors' concepts of the genesis of the electrocardiogram found in pericarditis. It is based on experimental studies of the authors in the dog and monkey. They found a lack of relationship between the alterations in the electrocardiogram and the morphology of the myocardium. They conclude that electrocardiographic changes in pericarditis depends on changes at the surface of the heart. This conclusion is at variance with the mass of evidence obtained by others.

Atomic Energy. By Karl K. Darrow, Ph.D. Being the Norman Wait Harris Lectures Delivered at Northwestern University. Cloth. Price, $2. Pp. 80, with 13 illustrations. John Wiley & Sons, Inc., 440 4th Ave., New York 16; Chapman & Hall, Ltd., 37-39 Essex St., Strand, London, W.C. 2, 1948.

The author of this book was invited to present the subject of atomic energy in four lectures to an audience who were not physicists. This problem has been pretty well solved, for the material is readable and interesting without being superficial. A number of tables supply concrete details as food for thought without detaining the reader unduly. For many persons it will be a welcome introduction to a difficult but important subject.

Queries and Minor Notes

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any official bodies unless specifically stated in the reply. Anonymous communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

ACCIDENTAL EXPOSURE TO LEPROSY

To the Editor:—I was testing a leper for skin anesthesia and accidentally stuck my own arm with the pin. About twenty minutes later I cauterized the site with sulfuric acid. Do you think it would be advisable to take a course of sulphetrone© (4:4'-bis [gamma-phenyl-N-propylamino diphenyl-sulfone-tetra sodium sulfonate]) or some other suitable drug as a prophylactic? If so, how much do you recommend?

R. S. Newbold, M.D., Belgian Congo.

Answer.—The inquiry does not state whether leprosy bacilli were recovered from the skin of the patient in question. The presence or absence of organisms in the skin is of paramount importance. The chance of transferring the infection from a negative case is considered to be nonexistent; if, on the other hand, organisms could be recovered from the skin the chance of transferring the infection is at least theoretically present.

From the numerous instances recorded in the medical literature in which deliberate experimental attempts of transmitting leprosy from infected to healthy persons by direct inoculation have resulted in failure to transmit the infection, it would appear that in this instance the possibility of leprosy transmission is exceedingly remote. The examiner's arm was apparently stuck only once with the questionably infected needle and the point of contact was later cauterized with sulphuric acid. In the instances of the experimental attempts at transmitting the infection, repeated inoculation were made and, of course, no attempt at destroying the inoculant was made. Yet evidence of infection in these experimental attempts (some 140 odd) recorded in the medical literature did not occur.

There are instances of accidental infection with leprosy reported. Rogers and Muir in a textbook on leprosy (Leprosy, ed. 3, Baltimore, William Wood & Company, 1946) listed several instances of accidental inoculation including that of Marchaux, who in 1922, while operating on a leprosy patient, pricked the finger of his assistant, in whom leprosy developed after several years. A case reported by Lagandaky in 1936 is also mentioned. This patient received repeated injections of blood from a patient with leprosy, and in less than two months after his first inoculation cutaneous lesions of leprosy were developed. In the face of such reports it is understandable why concern should be shown by any one who feels that accidental inoculation has taken place, although such an inoculation might be of the most superficial kind.

Since drugs of apparent chemotherapeutic activity against leprosy are available in the sulfones, it is also probable that they would be of prophylactic value against the development of the disease. So far no instance of their use prophylactically has been reported. On leprous lesions the action of the sulfones is found to be slow but certain. It is felt that these drugs are capable of preventing the formation of new lesions, allowing the old lesions to disappear much in the same manner as occurs during spontaneous recovery from the disease. The exact mechanism whereby this therapeutic activity is accomplished is not known, but there is a suggestion that if sterilization does not occur at least a reduction of leprosy bacilli in the blood stream occurs after the use of the sulfones. The latter occurrence is probably the most tenable because the action of the drugs under no circumstances is rapid, and prolonged administration of the drugs is necessary for any considerable clinical improvement.

In the present instance although the likelihood of infection is exceedingly remote it is present and cannot be ignored. The recommendation of one of the sulfones on a prophylactic basis would imply that the mechanism of their action is more or less completely understood. Furthermore, their use for such a purpose from the experience gained in the treatment of leprosy would have to be of rather prolonged duration. It therefore would appear that a more practical solution of the problem in this case would have been excision of a small area of skin at the point of inoculation followed by some form of cautery. That some organisms have reached the blood stream is a rather remote possibility and probably of no higher occurrence than is experienced by leprosy workers in general in their routine daily work and successfully combated by the body defense system. If there is an indication that the frame of mind against fear of infection can be bolstered by the use of the sulfones their use might be of benefit; there is no particular contraindication to their use as they are of fairly low toxicity and if used with discretion can cause no harm. An unequivocal scientific recommendation for the use of the sulfones prophylactically must await such basic consideration as the cultivation of the leprosy bacilli on artificial mediums followed by in vitro and in vivo studies of the effect of these drugs on the organism. Before that is done the use of sulfones prophylactically cannot be recommended except on an empiric basis.

OXYGEN SATURATION OF HEMOGLOBIN

To the Editor:—Mutch in 1940 reported the alveolar concentration of oxygen by various means of administration as follows: normal, 15 per cent; nasal catheter, 30 per cent; tent (usual), 45 per cent; tent (extreme), 60 per cent, and B. L. B. mask, 90 per cent. What are the comparable blood concentrations of oxygen in the pulmonary veins or peripheral arteries by these methods in normal conditions, cardiac embarrassment, burns, shock, atelectasis and other diseases restricting the tidal air volume of the lungs?

R. A. Davison, M.D., Hendersonville, N. C.

Answer.—Some of the basic physiology concerned in this question is to be found in "The Principles and Practice of Inhalation Therapy" by A. L. Barach (Philadelphia, J. B. Lippincott Company, 1944), and appropriate chapters in "Physiologic Basis of Medical Practice" by Charles H. Best and Norman B. Taylor (Baltimore, Williams and Wilkins Company, 1945).

Rather than speak of oxygen concentration of the blood, it is preferable to direct attention to oxygen saturation of the hemoglobin in the blood. The oxygen in the blood is presumably in equilibrium with the oxygen in the alveolar air, as is also true for carbon dioxide. However, the concentration of oxygen in the alveoli depends on the partial pressure also exerted by the carbon dioxide and the water vapor in the alveolar air and the efficiency of the lung in ventilating the terminal alveoli, as well as on the concentration of oxygen in the air breathed.

Because of the peculiar dissociation curve of a hemoglobin-oxygen mixture in the face of various carbon dioxide tensions, the oxygen saturation of hemoglobin does not vary directly with the oxygen tension in the alveolar air. Correction of the acid-base imbalance present in nearly all of the listed states is at least as important as furnishing oxygen in the inspired air.

In the last analysis, the choice of mode of oxygen administration depends on the method which will supply the most oxygen and permit optimal pulmonary ventilation while other treatment is directed toward the underlying disease.

CODEINE ADDICTION

To the Editor:—A patient suffering intense pain in arms, legs, neck and head of unknown origin or causation was started on codeine hypodermically by another doctor. She had been taking large amounts of acetylsalicylic acid but without much relief. She was taken to Chicago and found to be allergic to most of the common foods and a few drugs. Her condition is better than a year ago but she still requires several injections of codeine daily. I have been told that it is not difficult to take a patient off codeine when the need for it no longer exists. Is this true? What can I use in place of codeine to relieve her pain?

M.D., Ohio.

Answer.—After need for the drug no longer exists, relief of the rather mild physical dependence created by prolonged use of codeine is simple. Codeine has been included in the group of drugs under control of the Bureau of Narcotics mainly because addicts, or potential addicts, not satisfied with the action of this drug, change to one of the more dangerous opiates or to substances whose action resembles that of the opiates.

As with all attempts at withdrawal from a substance on which a person is in any way dependent, complete control of the patient's environment is necessary but, of course, frequently difficult or impossible. With assurance that the patient has no access to any substance not prescribed, or given, by the physician, an occasional dose of codeine for several days, reducing rapidly the size of the dose, will insure that no great discomfort will be felt by the patient. A serious possibility is that a patient is also taking some other drug, e. g., a barbiturate; if there is definite physical dependence in this group, sudden withdrawal may be followed by a grand mal seizure, so severe as to cause fracture of a femur, or serious compression fracture of one or more vertebrae.

Several things in the question need amplification. Nothing is given as to how large the "large amounts" were, or as to what the present daily dosage is. "Intense" pain is not usually relieved by codeine. Pain of the character and in the distribution described is often encountered as a part of a severe abstinence syndrome for morphine. There should, however, be other manifestations of this syndrome, e. g., yawning, goose flesh, restlessness and, in the more severe stages, vomiting and diarrhea and, finally and most serious, hyperpyrexia (105 F. and above).

Intensity of pain is difficult to measure. What might be an annoying discomfort to one person, to another would be an agonizing pain. Results of prefrontal lobotomy suggest that the interpretation of the severity and significance of a pain is in large part a function of the prefrontal lobes.

It is possible that the patient, without the knowledge of her physician, is taking some other drug with morphine-like action. If her supply became exhausted, some such complaint (real and not assumed) might lead her to demand relief.

Since the cause of the pain so far remains unknown, it is difficult to suggest a remedy. There are many analgesics that have only slight addictive risks.

There is a synergistic action between nearly all analgesics and members of the barbiturate group; a combination of small amounts of each will frequently give better results than either alone in much larger amounts. Wolfe has showed that the probable basis for this is a "chain reaction" started by a small focus of pain, and spreading widely through the muscles. Of course, barbiturates must also be given with care, especially to a patient whose "intense pain" is relieved by codeine.

The proper procedure, if it can be followed, is to place the patient in an environment where the physician can be absolutely sure that unauthorized medication is not obtainable; then follow this by a thorough study for possible causation. Without an approximation of such control of medication, the physician can never be certain that his patient is not complicating the situation by the use of too much of the same or of some other substance.

SOLVENT CONTACT DERMATITIS

To the Editor:—A macular papular diffusely erythematous rash developed first on the patient's face and neck, with burning, stinging and some itching. In two days the rash spread over his face, trunk and upper extremities, being less severe on his hands and lower extremities. The skin became indurated and slightly edematous. Considerable symptomatic relief was obtained with 50 mg. tripelennamine hydrochloride, four times daily. Considerable desquamation accompanied improvement. A history was obtained of a similar but more localized rash occurring ten months previously after he had spilled fuel oil over his abdomen. Three days prior to the generalized eruption he had started working for a highway construction company cleaning asphalt from buckets and equipment with some solvent thought to be gasoline; stinging of the face and neck was noted shortly after the first exposure to these substances. Could such a rash be due to this industrial exposure, and is it proper to call it an exfoliative dermatitis?

William C. Crothers, M.D., Salem, Ore.

Answer.—Contact with a solvent or fuel oil might well produce such an eruption in a patient who is hypersensitive to the materials. Such an eruption is more apt to be an acute contact type dermatitis rather than exfoliative dermatitis, which is characterized by generalized hyperemia, inflammatory infiltration, exfoliation, edema of soft parts, as the neck, eyelids and flexures, and a skin that is smooth, shiny and red where the scales have been removed—all accompanied by considerable chilliness.

SCHIZOPHRENIA

To the Editor:—A white man aged 41 consulted me recently because of fear of insanity. He has always been in good health. No history of insanity occurs in parents or maternal and paternal grandparents. He has a mild anxiety neurosis, fear of fainting since having a sensation of lightheadedness about ten years ago, but otherwise is normal mentally. His sister, aged 36, has recently been committed to a mental hospital because of schizophrenia. What are his chances of developing schizophrenia?

M.D., Ohio.

Answer.—At his age, with negative history in parents and grandparents, almost none.

TOUPEE PASTE

To the Editor:—Are there carcinogenic properties in spirit gums used to hold toupees to the skin?

M.D., Pennsylvania.

Answer.—The essential ingredients apparently are substances such as gum arabic, or tragacanth, which may produce dermatitis. Cancer has not been reported to be caused by these substances.

TUBERCULOUS PLEURAL EFFUSION

To the Editor:—A patient, aged 53, in a sanitarium because of mild schizophrenia experienced typical pleural pain. Roentgenograms of the chest at the outset were normal in appearance. Fever and other abnormal findings were absent. Laboratory data were negative except for a moderate increase in the sedimentation rate. After a week the pain subsided, but a gradually increasing pleural effusion occurred. Before thoracentesis was performed a spontaneous pneumothorax also occurred. Examination of the fluid initially was negative for organisms. Cultures were negative, but specific gravity and the protein content, as determined in the usual examination, indicated that a transudate was present. Examination for tumor cells was negative. Several weeks after subsequent thoracenteses the laboratory reported acid-fast organisms found by direct smear, culture and guinea pig inoculation. Both the pneumothorax and pleural effusion remain after six weeks. Is daily closed drainage with effort to remove the air indicated? Should streptomycin be injected into the pleural cavity after thoracentesis (also penicillin) as prophylactic against empyema? The apexes of both lungs still appear normal. Tuberculosis is not evident elsewhere. Roentgenograms after the pneumothorax occurred showed adhesion of the middle lobe and the lateral chest wall.

M.D., Washington.

Answer.—With pain as the first symptom, one might suspect spontaneous pneumothorax or pleuritis. In the beginning, either of these conditions may escape detection on the roentgenogram. So little air may have accumulated in the pleural space that it would not be visible to ordinary roentgenographic film inspection. Moreover, recent localized inflammation of the pleura cannot be visualized on the roentgenogram. It is assumed that the second roentgen inspection of the chest of your patient was not made until one week after the onset of symptoms. By this time enough air could have escaped through a minute rupture in the visceral pleura so as to be readily detected by roentgen ray. Visceral pleural blebs are a frequent cause of spontaneous pneumothorax in the absence of demonstrable evidence of disease in the lungs during life or even at postmortem examination. In such cases pleural fluid may accumulate in the pneumothorax cavity.

Another possibility is that a subpleural pulmonary lesion, too small to be seen by roentgenographic inspection or located in an area not clearly visualized, may have eroded or extended into the visceral pleura, resulting in inflammation of the parietal pleura with pain. If the condition were tuberculous this would be adequate to result in pleural effusion. Moreover, the subpleural lesion may have eroded through the visceral pleura so that air was readily admitted to the pleural space from the lung. Under such circumstances large numbers of tubercle bacilli may also be admitted to the pleural space.

Acid-fast bacilli are not always tubercle bacilli, even under these circumstances. However, with good laboratory technic there can be no doubt that those recovered from the fluid of this patient were tubercle bacilli, as the best known test for pathogenicity, namely, animal inoculation, was used. Failure to find tubercle bacilli when the fluid was first detected is not unusual. In fact, this often occurs even though a sizable number of specimens are examined.

If the pneumothorax is not large enough to cause pressure symptoms or extensive collapse of the lung with areas of atelectasis, removal of air is not indicated, as the creation of an excessively high negative pressure in the pleural cavity might keep the fistula open longer than if the air is allowed to slowly absorb. The relaxation of the lung resulting from the pneumothorax may permit a more ready closing of the fistula. In such a case, however, the removal of fluid as indicated to keep the pleural space as dry as possible not only will permit the lung to reexpand faster, but may also help in preventing empyema. Mixed infection empyema sometimes occurs in such cases when organisms admitted to the lung through the bronchi enter the pleural space through the fistula. Rarely is infection produced by careful aspiration of the fluid. There is no harm in introducing penicillin after each aspiration, and it may serve to destroy organisms which might otherwise result in a mixed infection empyema.

Although streptomycin has been administered in a limited number of cases of tuberculous pleurisy with effusion, it is probably better to refrain from its use in the case described. At best it has only a bacteriostatic effect. Moreover, there is strong likelihood that during the course of streptomycin therapy a preponderance of resistant tubercle bacilli would be found. Resistance to streptomycin apparently is passed on to the descendants of tubercle bacilli, and therefore if later a more serious condition should develop, such as meningitis or miliary disease, streptomycin would probably be of little avail, whereas it is usually of considerable help in suppressing such disease in persons who have not previously had a course of this drug. It is generally agreed that in tuberculous lesions anywhere in the body which usually respond well to other forms of treatment, streptomycin should not be administered.

It should be held in reserve for those conditions which do not respond well to other methods of treatment.

In all probability the right lung in the region of the middle lobe did not become adherent to the chest wall within a week after the pain appeared. It is more likely that involvement of the pleura had been present for some time. Whether the bronchopleural fistula occurred at or near the site of the pleural adhesions might be determined by thoracoscopic inspection. However, there is no point in doing this unless the fistula should remain open and surgical closure be indicated later.

Unless the fluid and air were under considerable positive pressure they probably did not cause rupture of an adhesion resulting in the fistula. It is more likely that this was due to subjacent disease extending through the pleura.

UNILATERAL MYDRIASIS

To the Editor:—**A 7 year old Negro boy noted dilatation of the right pupil on arising four days prior to examination. Systemic disease is not evident. The fundus appears normal except for a hyperemic macula area. History of head injury or headaches is absent. As far as the eye is concerned, the patient is asymptomatic. Please suggest causation and treatment.**

J. E. Calloway, M.D., Louisville, Miss.

Answer.—Unilateral mydriasis, in general, may be due to a lesion of the intraocular muscles, an irritative lesion of the sympathetic nerves or an interruption of the third nerve at the Edinger-Westphal nucleus, the nerve trunk itself or the ciliary ganglion.

Direct injury to the eye may cause dilatation of the pupil and loss of response to light and accommodation—convergence. The pupil usually remains dilated for only a few days, but occasionally may remain dilated permanently. Irritative lesions of the sympathetic nerve, known to cause unilateral pupillary dilatation, are pulmonary tuberculosis of the apex, tuberculosis of a cervical lymph node, bronchiectasis, gangrene of the lung and pneumothorax.

The third nerve nucleus or trunk may be involved in juvenile paresis, temporal lobe tumors, tumors of the pineal gland, subarachnoid or subdural hemorrhages or rupture of middle meningeal artery and following mumps, meningitis, diphtheria and anterior poliomyelitis.

Mydriasis with paralysis of accommodation is caused by atropine, homatropine, scopolamine and to a partial degree by eucatropine hydrochloride. Mydriasis without involvement of accommodation is caused by epinephrine and its derivatives and cocaine and its derivatives.

Congenital mydriasis is infrequently seen, as in hysteria, with associated amaurosis or amblyopia. Dilatation may occur as an associated reaction when strong attempts are made toward voluntary movements of the eye in any direction or attempt is made to diverge. It has been described in schizophrenia. The tonic pupil of Adie is characterized by unilateral dilatation, slow reaction to light and absent tendon reflexes.

Once it is determined whether the lesion is in the intraocular musculature, the parasympathetic or sympathetic nerves, the diagnosis is simplified. Usually a local lesion is associated with other signs of disease or injury of the eye. There is a prompt consensual pupillary reaction, accommodation may or may not be affected and the pupillary reaction to drugs is inconstant. Dilatation due to sympathetic irritation is characterized by response of the pupil to light directly and consensually, normal accommodation and normal response to physostigmine salicylate. Third nerve involvement is characterized by loss of accommodative power, frequently loss of the direct and consensual pupillary reaction and decreased or absent miosis following treatment with physostigmine salicylate. Treatment must be directed toward removal of the cause.

APOMORPHINE SOLUTIONS

To the Editor:—**Is apomorphine hydrochloride in sterile water or isotonic sodium chloride solution a stable preparation? If not, what solvent may be used for a stable hypodermic solution?**

C. C. Horton, M.D., Pendleton, S. C.

Answer.—Aqueous or alcoholic solutions of apomorphine hydrochloride are unstable, gradually acquire a green color, and lack therapeutic properties. The addition of 0.05 per cent sodium bisulfite may be useful as a preservative.

Solutions containing the methyl bromide derivative euporphin® (apomorphine methyl bromide) have been reported to be more stable than the salts of apomorphine. A clear solution containing apomorphine, ascorbic acid and mannitol has been reported (*Chem. Abstr.* **41**:1809, 1947) which does not undergo color change.

TEST FOR UROBILINOGEN

To the Editor:—**What are the reagents and the technical procedure in performing the Wallace-Diamond urobilinogen test on the urine?**

M.D., North Carolina.

Answer.—Prepare the reagent by dissolving 2 Gm. of paradimethylaminobenzaldehyde, preferably Eastman's, in 100 cc. of 20 per cent (by volume) hydrochloric acid (20 cc. conc. HCl + distilled H_2O ad 100 cc.).

Urine for test should be fresh. After standing, especially in light, urobilinogen is fairly rapidly changed to urobilin. Bile pigment, if present, should be removed by adding 1 part of 10 per cent aqueous solution of calcium chloride to 4 parts of urine and filtering or centrifuging, or by adding a small amount of calcium chloride crystals instead of the solution, followed by filtration or centrifugation.

To 10 cc. bilirubin-free undiluted urine at room temperature add 1 cc. Ehrlich's reagent and allow to stand three to five minutes. If a deep cherry red color appears proceed with diluted urines. Normal urines produce a moderately deep red color.

Prepare serial dilutions of urine, 10 cc. of each, of $\frac{1}{10}$, $\frac{1}{20}$, $\frac{1}{40}$, etc., with distilled water or tap water. Add to each tube 1 cc. of the reagent and allow color to develop for three to five minutes. Look down tube through the column of liquid against a white background, preferably by daylight. The result is expressed in terms of the highest dilution which shows a faint pink color. Most normal urines show color at one-tenth and in the afternoon, especially, some show color at one-twentieth dilution.

Watson's method may be used also and is more strictly quantitative.

PROSTATIC CANCER AT AGE SEVENTY

To the Editor:—**What is to be preferred in cancer of the prostate in a man of 70 plus? Should he be treated only with diethylstilbestrol or estynil® (ethinyl estradiol), or is orchiectomy advisable, and when? What is intracapsular orchiectomy, and does it give longer life than complete castration? Should the prostate be removed and by what method?**

J. W. Hopkins, M.D., Glendale, Calif.

Answer.—Carcinoma of the prostate gland in a patient 70 years of age is generally a slowly growing tumor, and the most conservative treatment that is effective is indicated. Estrogenic substance is a treatment of choice and administration of it should not be delayed when the diagnosis of carcinoma is established. Tolerance to the estrogens is variable and the dosage must be adjusted as indicated. Orchiectomy is reserved for patients wholly intolerant of estrogens and for those patients in whom the effectiveness of the estrogens has been dissipated. Intracapsular orchiectomy does not have advantage over castration. Although endocrine secretion has not been definitely ascribed to the epididymis, excision of the testicle and epididymis will preclude any possibility of androgen stimulation of the carcinoma by these organs. Androgenic substances of adrenal origin must be neutralized with estrogens. In a man 70 years of age with carcinoma of the prostate, transurethral resection of obstructing prostatic tissue is the only type of prostatic surgery indicated. It is only the small, early nodule of prostatic cancer that is amenable to radical perineal prostatectomy and then only in a younger age group.

INDUSTRIAL CARBON TETRACHLORIDE HAZARD

To the Editor:—**A young veteran who has gone into the dry cleaning business becomes violently ill every time he inhales the fumes of carbon tetrachloride. He even becomes nauseated at the thought of it. Is there any type of mask that will filter out these fumes?**

M.D., New Jersey.

Answer.—Dangers from carbon tetrachloride are real and, provided the exposure is sufficient, are more substantial than nausea and vomiting. At and somewhat below 50 parts per million the damage is largely on a nonorganic basis. Above that level, and particularly above 100 parts per million, serious organic injury may arise, notably to the liver and kidneys. In the avoidance of possible harm in the dry cleaning industry, reliance for continuous purposes on protective breathing apparatus, including positive pressure respirators, is impractical. The use of such appliances should be limited to special operations such as the cleaning out of sump tanks. Equipment for carbon tetrachloride dry cleaning is readily available that prevents frequent escape of toxic vapors. In fact, closed systems are essential both to the conservation of health and to avoid the uneconomic wastage of the expensive carbon tetrachloride. If the equipment ostensibly of the closed system type still emits some vapors that may not be avoided, local exhaust devices should be installed to remove such vapors.

In the present instance the practical need is to have the state's Bureau of Industrial Hygiene carry out suitable determinations of the carbon tetrachloride in the atmosphere and to determine the source of such intoxicant. Remedial steps should seek to maintain atmospheric levels at or below 25 parts per million and *certainly not higher than 50 parts per million. In* the possibility of high individual susceptibility, this present dry cleaner may find it expedient to substitute for the chlorinated detergents such as carbon tetrachloride, one of the recognized petroleum derivatives. More dry cleaning is carried out with naphtha types of dry cleaners than with carbon tetrachloride. However, naphtha dry cleaners are not entirely without their own hazards and in addition are subject to fires. While the wearing of respirators in this operation is not encouraged, suitable information may be obtained from many manufacturers, including the Mine Safety Appliances Company, Pittsburgh.

ALCOHOL INTOLERANCE

To the Editor:—A 49 year old man weighing 190 pounds (86.2 Kg.), in good health, states that for the last year he can no longer take alcohol without becoming dizzy and perspiring. He also becomes more talkative and inebriated. Up to a year ago he could take as much as 26 ounces of alcohol over a period of a few hours without feeling intoxicated. Then after a meal he was again normal. Now he dreads the effect of 2 ounces of alcohol and the effect lasts for much longer periods of time. The kind of beverage he takes does not change results. He has been taking alcohol in large amounts for the last twenty-five years, on some weekends or holidays. Is there a pathologic explanation for my patient's becoming so intolerant and in so short a time? What do you suggest to improve his tolerance?

La Salle Mondor, M.D., Grand'Mere, Quebec, Canada.

ANSWER.—The original high tolerance for alcohol may actually have been a symptom of brain damage. The Report of the Advisory Committee of the Central Control Board (Liquor Traffic), appearing in "A Review of The Effects of Alcohol on Man, London, Victor Gollancz, Ltd., 1931 (p. 64) states: "From the point of view of general health the acquisition of tolerance really implies the removal of a protective mechanism—it allows the drinker to use the drug in doses which he could not have taken if his brain cells had retained their normal power of reacting to it." "These facts suggest that the acquirement of tolerance or, as Hansen terms it, of 'Functional habituation' by the nerve cells is a pathologic change and represents the first stage of chronic alcoholic poisoning."

The sudden loss of tolerance with the acquisition of extreme susceptibility occurs in persons who are on the verge of one of the diseases of alcoholism such as the polyneurotic Korsacow pattern or delirium tremens. The patient is indeed fortunate to have acquired the dislike for alcohol, and he certainly should not be encouraged to increase his tolerance. Lucky is the man for whom the bell tinkles before it tolls.

CHRONIC MULTIPLE SCLEROSIS

To the Editor:—A patient with chronic multiple sclerosis has been taking liver and B-complex injections for years. The disease has been progressing slowly but steadily during this period. I understand that there has occurred an "associated low grade anemia" but not of the pernicious anemia type. 1. Is there value in the continued use of liver and B-complex injections? 2. Will iron or molybdenized iron do as much for the patient's blood picture? 3. Do any of the following have any effect on ameliorating the disease: (a) tetraethyl ammonium chloride, (b) ephynal acetate® (d,l-alpha tocopheral acetate), (c) vitamin B-12 (reported in connection with the neurologic phase of pernicious anemia), (d) a combination of liver, folic acid and stomach extract or (e) injections of fibrolysin? 4. Are there any other agents which will aid in either the disease or the comfort of the patient?

Lester J. Candela, M.D., New York.

ANSWER.—Liver and B-complex injections in patients with multiple sclerosis have been widely used in the past, without resulting in any specific type of improvement in most patients. The feeling, however, that patients are "better" under this form of treatment is recognized by many. Relapses are frequently less severe than might be expected and some "resistance" develops, often vague but nevertheless discernible by competent observers. To many physicians, patients with multiple sclerosis show less severe symptoms than those seen twenty years ago before the use of liver or vitamin therapy was instituted. Such a point of view is not consistent with the views of some, but many neurologists are impressed with the value of vitamins, although less so with the importance of liver.

In patients with anemia, there is always the possibility that the symptoms are due to combined system disease and not to multiple sclerosis. The clinical signs are frequently similar enough to be confusing, but a first-zone colloidal gold reaction in the cerebrospinal fluid should never be found in combined system disease. Iron and liver, vitamin B_{12}, folic acid or stomach extract are indicated in the anemias with neurologic complications, but their value, if any, in multiple sclerosis awaits confirmation. Rest periods, appropriate exercises, warm climate, adequate diet, freedom from infection, a full vitamin intake, fully absorbed, and psychotherapy are the best forms of treatment for patients with multiple sclerosis at the present time.

LICHEN PLANUS

To the Editor:—Please furnish information relative to recent advancements in therapy of lichen planus.

M.D., Wisconsin.

ANSWER.—Therapy of lichen planus has not been greatly advanced. Recently, the use of sodium bismuth triglycollamate has been advocated, one tablet being given four times a day by mouth until relief is obtained or for a period of several months. According to the pharmaceutical house putting out this tablet under the trade name bistrimate,® one tablet contains 410 mg. of the drug, equivalent to 75 mg. of bismuth. Bismuth has been given in the past in the form of intramuscular injections of various bismuth salts and also in the form of bismuth arsphenamine sulfonate. Mercury in the form of protiodide, grain 1/6 (about 0.01 Gm.) three times daily by mouth, has also been recommended. Better results from the use of mercury followed the intramuscular injection of 1 per cent mercury bichloride in isotonic sodium chloride solution, the dosage varying from ⅛ to ¼ grain (about 0.008 to 0.016 Gm.) every second day. Twelve to twenty injections suffice when the treatment is effective. There are a great many other forms of therapy for lichen planus, including filtered roentgen irradiation to the paravertebral regions. No one type of treatment is successful, and in many cases lichen planus proves resistant to multiple types of treatment.

STREPTOTHRIX CASTS IN TEAR DUCT

To the Editor:—A young woman, aged 30, has had blockage of the right tear duct for several years. This condition gradually gets worse and then improves with the expulsion of a cast from the right tear duct. The cast is composed of Streptothrix organism. As gross concretion in the canaliculus is absent, surgery has not been performed. Have you suggestions for preventing the formation of these casts?

M.D., California.

ANSWER.—Streptothrix organisms usually form concretions in the lower canaliculus causing pronounced dilatation of this structure. Prompt cure is ordinarily obtained by expressing the concretions on two or three occasions. Lugol's solution (strong iodine solution U. S. P.) can be instilled into the punctum. Obstruction of the nasolacrimal duct by this organism is unusual and as a rule requires extirpation of the lacrimal sac or dacryocystorhinostomy.

OTITIS EXTERNA

To the Editor:—Please give a résumé of causation, diagnosis and treatment of otitis externa. Is swimming sometimes forbidden as a preventive measure? Does the wearing of ear plugs help?

M.D., New York.

ANSWER.—Otitis externa is frequently due to a fungus. Aspergillus is often an offender. Bacillus pyocyaneus or Staphylococcus aureus may be responsible.

For the Aspergillus, cleanliness and use of cresatin or methylosainline chloride are recommended. For the B. pyocyaneus, dibromosalicylaldelyde in a 1 per cent solution is effective. For the Staph. aureus, 5 per cent sodium sulfathiazole is the treatment of choice. Moisture in the ear usually precedes the infection; most of these cases date from swimming in the summer. Lamb's wool smeared with petrolatum to make a tight ear plug is useful for protection.

TEST FOR PHEOCHROMOCYTOMA

To the Editor:—It has recently come to my attention that tetraethyl ammonium chloride may be of some value in the diagnosis of pheochromocytomas of the adrenal gland. This drug normally produces a fall in blood pressure when administered to a person having normal blood pressure or one having hypertension from causes other than adrenal tumors; whereas, when it is administered to a person having a pheochromocytoma, an immediate rise in pressure with accompanying symptoms will occur. Can this drug be used for that purpose? What is the suggested dosage?

L. C. Bailes, M.D., Anderson, S. C.

ANSWER.—Tetraethylammonium chloride has been utilized in making diagnosis of pheochromocytoma. The phenomena described in the question occur when pheochromocytoma is present. The total dosage for this diagnostic purpose is 300 mg.

PROTEIN COMES INTO ITS OWN

The Frank Billings Lecture

JAMES S. McLESTER, M.D.
Birmingham, Ala.

The science of nutrition as I have watched it develop through the years has presented a constantly changing picture. According to the trend of research and the appeal to the imagination made by the discoveries of the day, first one coloration and then another has dominated the picture. This development can roughly be divided into five periods, all culminating today in a period of greater appreciation of protein.

THE ENERGY ERA

First, there was the energy era, the day of the great pioneer students of metabolism, of Liebig and Voit, and then of Rubner and Atwater, Friedrich Müller and Graham Lusk. The brilliant discoveries of that period had their beginnings in Paris with Lavoisier in the investigations which led him to the conclusion that all life is a chemical process. The scientists who followed Lavoisier, notably those of the Munich school, were primarily interested in the chemical changes that take place in the body under the influence of living cells. Almost all of what we regard today as fundamental in metabolism was brought to light by these men. It was this generation of workers who discovered that the law of the conservation of energy is applicable to nutrition, that the nitrogen of the urine can be taken as a measure of protein destruction, that nitrogen equilibrium can be maintained by an appropriate diet, that muscle work does not appreciably increase protein metabolism, that foodstuffs may under given conditions replace each other in accordance with their caloric value (the isodynamic law) and that the heat value of basal metabolism is proportional to surface area. The standard caloric values of carbohydrate, protein and fat as determined at that time by Rubner and subsequently modified by Atwater are used today in all nutritional reckonings. Animal calorimetry had its beginning at that time; methods for measuring respiratory metabolism were perfected, and the Atwater-Rosa-Benedict calorimeter, which has served as the model for many subsequent forms of apparatus, was developed. The intricacies of metabolic disorders were studied and such diseases as gout and diabetes obtained a better understanding. During this era prime consideration was given to energy exchange, and attention to calories came first. In a later period, calories came perilously near being forgotten.

THE PERIOD OF ADEQUACY IN DIET

A little later came an era that may appropriately be called the period of adequacy in diet. Elvehjem recently remarked on the contrast between the liberal space given the regulation of the diet in the "corpus" of Hippocrates and the neglect of this subject in favor of drug therapy in the succeeding centuries. This neglect has continued almost to our time. Notwithstanding the wealth of information concerning the harmful effects of starvation uncovered by the investigators of the nineteenth century, physicians of the early years of this century continued to give little thought to the nutritive requirements of the sick person. They told the patient what he must not eat, not what he must eat. Patients with typhoid, for example, were given each day only a few ounces of milk and a little thin broth, and some physicians did not believe in giving milk! The plight of these patients, as I can testify, was grievous in the extreme. The distastrous effects of such a diet were not appreciated until the first decade of this century, when the error of dietary neglect became apparent notably in respect to two diseases, typhoid and peptic ulcer. I recall hearing Friedrich Müller in 1908 tell his students of the enormous tissue waste produced by the infection and resulting fever in typhoid and state that much of this waste could be prevented if the patient was given more food. Simultaneously in this country, Shaffer and Coleman[1] reported their studies of metabolism in this disease and advised a more liberal diet. A few months later, Coleman[2] again proposed a radical change in the feeding of the typhoid patient. The prevailing fear that an increase in the amount of food would both injure the intestinal ulcers and bring the fever to a higher level continued among many physicians, however, until it was effectively disposed of a few years later by the studies of Coleman and DuBois.[3] Thereafter, a much more liberal diet was generally used in the treatment of all febrile illnesses. In typhoid the results were especially gratifying. The so-called typhoid toxemia was eliminated, the frequency of complications lessened, the period of illness shortened, much of the resulting disability relieved and the mortality greatly reduced. The difference was graphic. It marked a new epoch in the dietary treatment of disease.

A similar improvement, though not so striking, was accomplished early in this era when Lenhartz[4] discarded the old von Leube starvation diet, then used in the treatment of patients with peptic ulcer, and gave

these patients more food and when, shortly thereafter, Sippy[5] in this country devised his well known regimen. True, the Sippy diet still did not provide enough food as we see it today, but it provided a great deal more than the patient had been given previously and its adoption recorded a distinct advance in the treatment of peptic ulcer. From such lessons physicians learned that hardly anything can be cured by starvation. They have come to provide a more liberal diet in the treatment of many diseases, and, as a result, they often see a shorter illness and less debility.

THE ERA OF ECONOMY IN NUTRITION

The third era brought protein into disrepute, and it is just now recovering its good name. This was the era of economy in nutrition. It was the day of "intestinal autointoxication" when many physicians were prone to ascribe almost every ill to which human flesh is heir to protein decomposition products absorbed from the intestinal tract. This idea led the physiologist Chittenden[6] to study on himself the influence of a low protein diet. Subsisting on a diet that provided only about 40 Gm. of protein daily, less than half of the then accepted standard, Chittenden maintained better health than he had enjoyed before. The sick headaches, bilious attacks and rheumatic pains all disappeared, and he experienced a greater degree of vigor. He was greatly encouraged. He continued his studies on others, professional colleagues, student athletes and soldiers, and all his subjects fared well during their period of protein restriction, which was about nine months. A little later the Danish physiologist Hindhede[7] also became an ardent advocate of the low protein diet and, like Chittenden, cited personal experiences. He reported that he even felt weak after eating much meat. Benedict[8] was at first critical, but later, during the food shortages of the first World War, he conducted experiments on a group of students which led him to revise his former views; he concluded that economy in nutrition promotes physical well-being. Although these beliefs in the beneficial effects of parsimony in nutrition were not accepted by scientists generally, many adherents were found in the medical profession and in the general public.

Apparently, there were two faults in these human experiments which tended to make the conclusions fallacious. First, no control groups were used. To those who are familiar with the reports of attempts made during the recent World War to improve the vigor of workers in industry by giving them vitamin pills, it is evident that, if conclusions are to be drawn from the testimony of the subjects themselves, control groups are necessary. Second, the time element was entirely too short. Lusk saw the difficulty clearly when he wrote that, while these experiments proved that the allowance of protein may safely be reduced during many months to half or less of what habit or appetite suggests without impairment of health or strength, it remains to be seen whether this quantity of protein in the ration, which is not greater than the body would metabolize in starvation, is advisable as a program for the whole of one's adult life.

Animal experiments appeared to provide the answer, as may be seen from the studies of McCollum and Simmonds,[9] who called attention to the relatively short period, nine months, of the reported human experiments, which is approximately 1 per cent of man's span of life. They cited experiments on animals indicating that substandard diets will, as a rule, produce no evidence of deterioration in the physical condition of the subject until 5 per cent of normal life expectancy has been covered; after that the ill effects of the restricted diet become apparent. McCollum and Simmonds observed that diets which are just good enough to permit a young animal to develop in an apparently normal manner will, when adhered to sufficiently long, cause instability of the nervous system and early aging. It was stated further that any deviation from the quality of the protein moiety of the diet, even in slight degrees from the optimum, exerts a profound influence on the functioning of the nervous system and the life history of the animal. What would have been the life history of Chittenden's subjects if the low protein diet had been observed ten years rather than nine months?

Physicians were often influenced during this low protein era by the reports of experiments on animals that were interpreted to indicate that a high protein diet was damaging to the kidneys and arteries. It is pertinent to state first that much of the evidence cited cannot be ascribed solely to the protein quota of the diet because the rations used were defective in other respects. Second, there was little evidence of true nephritis, and the animals brought to maturity on these diets remained apparently healthy and robust, showed normal fertility and produced long-lived healthy young, thus measuring up to the best nutritive criteria. Third, the intake of protein in such experiments was in most instances enormous, much greater relatively than civilized man ever takes. The results of these experiments apparently are not applicable to man.

There is, however, no lack of evidence from observations on man, as may be seen from the testimony of Stefánsson.[10] In his life in the Arctic he became enthusiastic over the virtues of an exclusive meat diet. His physician Lieb,[11] after a careful study of the explorer, wrote that during Stefánsson's eleven and one-half years in the Arctic Circle for long periods he subsisted solely on meat and that while on this diet he experienced the highest degree of physical and mental well-being. Of like tenor is the testimony of Thomas,[12] who as a member of the McMillan Arctic Expedition of 1926 made a cardiovascular and renal survey of the Eskimos of northern Labrador and Greenland. He reported that these people, living on an exclusively carnivorous diet, showed no unusual prevalence of vascular and renal disease. Similar observations were made by Tolstoi[13] and by McClellan and

DuBois[14] on 2 healthy white men who lived for a year on an exclusive meat diet. These investigators reported at the end of a year that:

> . . . in these trained subjects, the clinical observations and laboratory studies gave no evidence that any ill effects had occurred from the prolonged use of the exclusive meat diet.

This seemed to dispose of the fear that a diet liberal in protein is fraught with danger to the kidneys and arteries.

The other fear entertained by many physicians, that of "intestinal autointoxication," was disposed of by Alvarez[15] in his critical review. While this physician reached the Scotch verdict of "not proved," the testimony that has accumulated since his summary of evidence justifies the verdict of "not guilty." This hastened the end of the era of protein economy.

THE VITAMIN ERA

The fourth era, the most colorful of all, was introduced when it was found that an animal cannot live on purified diets alone. This era was foreshadowed many years earlier by Eijkman's observation[16] that something in the bran layer of the grain will protect fowls against the polyneuritis they show when fed a diet of milled rice. It was again forecast in 1911 when Funk[17] recognized the existence of deficiency diseases as we understand them today. It was the latter investigator who coined the word vitamin ("vitamine").

The present widespread interest in vitamins apparently began in 1913 when McCollum and Davis[18] observed that young animals restricted to a diet of purified casein, starch and lard, with an appropriate salt mixture, would not grow unless butter fat or egg yolk were added to the ration. About the same time Osborne and Mendel,[19] pursuing their experiments with similar diets, reported that not only was growth retarded in the young, but a characteristic disease of the eye developed in the older animals. These epoch-marking studies pointed to the existence of an important principle which is essential to growth, a fat-soluble factor, for which McCollum suggested the name vitamin A. Then Funk's "beriberi vitamine" was given the name water-soluble vitamin B and was subsequently split into its several components. Holst, Chick, Mendel and others demonstrated the existence of still another water-soluble vitamin, which was subsequently isolated from lemon juice by Waugh and King[20] and became known as vitamin C. In 1922, through the work of McCollum and his associates,[21] vitamin D came into recognition, and the discovery of still other vitamins followed. These substances were produced in pure form and their functions defined with a fair degree of accuracy. Many intricacies of metabolism were unravelled, and the vitamin era came into full development.

The minerals have never fired the imagination of the public, or indeed of the profession, as have the vitamins, but during this period nutritionists have continued to emphasize the need for an adequate supply of minerals, notably of calcium and iron. More recently, the part played in the human economy by certain "trace elements" is being studied and encouraging results can dimly be envisaged.

Accompanying this development of the vitamin era was a reawakening of interest in deficiency diseases. This interest had its beginnings two centuries earlier when the English surgeon Lind demonstrated that lemon juice or orange juice would cure scurvy, the scourge of the sea. The importance of these disorders was shown again in 1880 when Takaki almost eliminated beriberi from the Japanese navy with a more liberal ration, and still again in the first decade of this century when Fraser and Stanton[22] in Java and Chamberlain and Vedder[23] and others in the Philippine Islands were able to prevent beriberi by the substitution of whole rice for the unpolished grain. Present day interest in deficiency diseases, however, began when Searcy[24] *in 1907 identified the strange* disease then epidemic in the South as pellagra; when a few years later Goldberger[25] predicated his pellagra-preventive factor, and when in 1937 Elvehjem and his associates[26] found that black tongue in dogs, the analogue of pellagra in man, can be cured with nicotinic acid. This last discovery gave great impetus to the study of deficiency diseases, and, with brilliant results, opened up an entirely new area of nutritional investigation. The field has been assiduously cultivated. The soil was rich and the yield has been excellent.

In the treatment of these disorders results have been graphic. The public caught the enthusiasm, and now every one knows about vitamins and wants them. They are bought over the counter at drug stores indiscriminately and in enormous amounts, with benefit to many and without benefit to others. As this enthusiasm levels out, however, certain conservative tendencies may be seen. First is the recognition by nutritionists that if a person is well nourished and his vitamin equipment adequate then no nutritional benefit will accrue from the further taking of these substances. Evidence to this effect can be found in a number of publications dealing with the nutrition and health of workers in industry, notably in a recent article published by the Council on Foods and Nutrition and the Council on Industrial Health of the American Medical Association.[27]

A second conservative tendency is seen in the recognition that man should, as a rule, take his vitamins in the form of natural foods. Important as vitamins are—vitally so in the treatment of deficiency states—physicians are now coming to the realization that for the simple maintenance of robust health one should secure these substances, not from the pharmacist, but from the grocer and the dairyman. Helpful guidance to this end is being provided by many investigators in their extensive contributions to the knowledge of food composition, notably by Elvehjem and his co-workers. The

vitamin era is being rounded out with a wholesome appreciation of the importance of simple, good food. A few nutritionists are even calling themselves "ham and egg nutritionists."

THE PROTEIN ERA

The picture changes, and today we are in the protein era. As Lewis[28] observed in his excellent review, the regard in which this foodstuff is held today is in keeping with the origin of the name, from the Greek "first" (πρωτεῖος). This greater appreciation of the value of protein received its first impetus about ten years ago when Rose[29] told of feeding experiments on rats that revealed the indispensability of ten of the known twenty-two amino acids. He demonstrated that it is possible to maintain life in the rat when a suitable mixture of amino acids is the only source of nitrogen. Shortly thereafter, Shohl and Blackfan[30] accomplished the same in infants. Later, the indispensability of certain of these bodies to man, as well as to the rat, was shown by Albanese and his associates,[31] who observed that when lysine and tryptophane were withdrawn from the human diet a negative nitrogen balance resulted, which condition could be corrected only by restoration of the missing substances. That amino acid deficiency has specific effects became evident in the discovery that the removal of arginine from the diet causes a notable reduction in spermatozoa in the seminal plasma and that the content of spermatozoa becomes normal again when this amino acid is restored to the diet. Such specificity is now recognized, and in the opinion of nutritionists amino acid deficiency will make itself felt even more promptly than vitamin deprivation. Differences among species no doubt exist, but the available evidence indicates that, qualitatively, the requirements of man and the white rat for amino acids are similar and that the table of dispensable and indispensable amino acids constructed by Rose from his experiments on animals can be applied without too many exceptions to man.

This availability of amino acid mixtures as a food has widened the nutritionist's horizon and has stimulated manifold animal experiments and clinical trials. There is still a question, however, as to whether a mixture of pure amino acids can completely and for all purposes replace the protein of the diet, for evidence has been presented suggesting the need under certain conditions for accessory factors which are themselves derived from the protein molecule. Elvehjem[32] expressed the opinion that the answer to this question depends largely on the age of the animal. Opportunities for the use of amino acids as a substitute for protein appear almost unlimited but, as this author stated:

> . . . In the light of the work on amino acid imbalance it is apparent that each amino acid must be supplied in optimum concentration before the need for accessory . . . compounds can definitely be settled.

There is still much to be learned regarding the proper concentrations of the individual amino acids to be used in such mixtures. It is stated, therefore, by the Council on Foods and Nutrition of the American Medical Association that amino acid mixtures and protein hydrolysates containing such mixtures should be reserved for use in those cases in which parenteral feeding is necessary. If the stomach is retentive, whole protein, such as is provided by milk, meat or eggs, should be given.

The part played by protein in the metabolism of the cell has been greatly clarified in recent years and some of our older concepts must be radically revised. The present opinion is that the proteins of the body cell are not the fixed parts of a permanent structure, like the steel framework of a building, but are labile substances in a constant state of change. The first evidence of this was seen in the experiments with isotopic nitrogen of Schoenheimer and Rittenberg,[33] who reported that the protein equipment of all living cells is subject to a rapid and continuous regeneration and that in spite of this constant chemical interchange the composition of the tissues remains surprisingly the same. A few years later, Whipple and Madden[34] also demonstrated that proteins are not held in the manner that carbohydrate and fat are stored, but exist rather in a highly mobile state in which their fractions are in constant exchange. The latter workers showed that the body maintains in the plasma and in the cells a large pool of circulating proteins which are in dynamic equilibrium, and that the contributions to this pool may concern any body cell needing protein or capable of storing surplus protein.

> . . . The circulating plasma protein is the medium of exchange and the body is solvent just so long as there [are] adequate protein supplies for any emergency. When the body becomes insolvent, there may be foreclosure due to disease, infection, or injury.

Physicians at the bedside have often witnessed such foreclosure.

Still further interest in protein has been stimulated by a host of recent clinical observations. Prominent among these reports is the testimony that has come from many sources telling of the pressing need in respect to protein of the pregnant woman and the nursing mother, as seen especially in report of Ebbs, Tisdall and Scott.[35] These authors told of remarkable benefits to both mother and child from a few simple additions to the diet. Bethell and his associates[36] saw a positive correlation between macrocytic anemia and an inadequate intake of protein, and Leverton and McMillan[37] wrote to the effect that a generous serving of meat given daily to pregnant women, in addition to their self-chosen diets, is effective in increasing hemoglobin and red blood cell concentration, avoiding edema and promoting lactation. Williams[38] concluded in his summary of evidence that:

> . . . It seems reasonably sure that pregnant women with *liberal intakes of protein seldom develop the specific toxemia* of pregnancy. . . .

38. Williams, P. F.: Importance of Adequate Protein Nutrition in Pregnancy, in Protein Nutrition in Health and Disease, Chicago, American Medical Association, 1945, p. 15.

No longer does the obstetrician tell his patient that to avoid eclampsia and the other perils of pregnancy she must restrict the protein of her diet; now he tells her that she had best eat an abundance of good protein.

There is evidence, too, that both the welfare and the proper development of the offspring depend in no small degree on the adequacy of the expectant mother's diet. Burke and her associates[39] concluded from their statistical studies in the department of child hygiene of the Harvard School of Public Health that there is a significant relationship between the diet of the mother during pregnancy and the condition of her infant at birth. From the same school came a report by Stuart[40] who, by means of roentgenograms, showed that proper osseous development at birth depends to a large degree on the suitability of the mother's diet and that protein is a factor in determining the adequacy of this diet.

Significant, too, are the reports which tell of the part played by protein in resistance to infection. Cannon[41] wrote of the dependence of phagocyte formation on plasma protein levels and cited the observations of Cottingham and Mills indicating that in rats a direct relationship exists between the amount of protein consumed and the efficiency of phagocytic activity. More important still is the part played by protein in antibody formation. Cannon pointed out that the antibody globulins of the blood are simply normal serum globulins which have been specifically altered and that adequate production of these is dependent on a sufficient intake of amino acids. He assumed, therefore, with good reason that antibody production is dependent on protein intake. This has been demonstrated experimentally by Cannon and his associates,[42] who observed that animals subjected to prolonged protein undernutrition exhibit a pronounced loss of the capacity to fabricate antibodies and to resist infection and that this loss can be quickly made good by addition to the ration of liberal amounts of good protein. Accumulating evidence indicates that protein plays a fundamental role in the maintenance of both natural and acquired resistance.

PROTEIN IN SURGICAL AND MEDICAL TREATMENT

One of the most interesting developments in the evolution of the protein era has been the awakening of surgical interest. In their article, Lund and Levenson[43] told of the large, sometimes enormous, nitrogen losses that have been reported in acute trauma and after surgical operations, and of the generally harmful effects of protein deficiency in surgical patients. Whipple[44] and others described the prolonged lag period in the healing of wounds and of the increased danger of wound rupture when protein nutrition is poor. Proof of this is seen in the animal experiments of Kobak and his co-workers,[45] who observed that the tensile strength of the abdominal wounds of protein-deficient rats was only one-third that of the controls. Elman[46] wrote of the severe shock that develops from surprisingly small losses of blood when the plasma proteins are already low. According to the studies of Mulholland and his associates,[47] even bedsores are more frequent when the plasma protein content is low, and the hypothesis is offered that these sores represent pressure necrosis in tissues which have been devitalized by protein deficiency. Surgical opinion today is in apparent agreement with Co Tui[48] when, from his studies of surgical repair, he concluded:

> Proteins are essential to wound healing, to the maintenance of tissue integrity, and from present indications, to expeditious convalescence. Protein deficiency endangers all three.

Medical opinion likewise has come to a wholesome appreciation of the need for liberal amounts of protein in the diet of the sick person. This trend apparently had its beginnings about fifteen years ago in the radical change which took place in the feeding of patients with Bright's disease. Aldrich and Boyle,[49] after observing 300 children with nephritis, impressed by the grievously ill state of most of them, discarded all preconceived ideas of diet and ordered meat or eggs three times daily. After two years' experience with this innovation, they reported that the majority of their patients showed definite clinical improvement and that the death rate was decidedly lower. At about the same time, McCann[50] also reported significant improvement in a group of nephritic patients after the allowance of protein was materially increased, in some instances doubled. Like reports came from other sources, and now patients with nephritis are fed with much greater consideration for their nutritive needs.

Less startling, but perhaps equally effective, was the introduction of more liberal amounts of protein in the diets of patients with peptic ulcer. Recently, Co Tui[48] reported early healing, with unusually prompt relief from pain and rapid gain in strength, in 29 patients with ulcers whose nitrogen intake, largely in the form of protein hydrolysates, was about three times that commonly allowed. Other physicians gave ground meat a prominent place in the diet for patients with ulcers and also reported encouraging results. Improvement follows in many other forms of illness when the physician induces his patient to eat more meat. This is particularly true of so-called neurasthenia. The treatment of syndromes of this character with an abundant diet, in which is included liberal amounts of protein, is often more effective than psychotherapy. This is equally true of the neurasthenic syndrome that accompanies many deficiency states. Pellagra as one ordinarily encounters it can seldom be cured completely by the administration of nicotinic acid and the other vitamins of the B complex alone. The patient needs good protein, and he rapidly regains his equi-

librium when he gets it. A more obvious illustration of the need for protein is seen in the nutritional edema described in this country by Youmans and his associates[51] and encountered throughout the world wherever food shortages prevail. Examples could be multiplied.

The most dramatic about-face, however, which has been accomplished in the recent history of nutrition has been in the feeding of patients with diseases of the liver. It was not many years ago that protein foods were regarded as especially damaging to the sick liver. Large quantities of carbohydrate were given to protect this organ and to promote repair. The fallacy of this treatment was pointed out less than a decade ago by Mann,[52] who from his experiments involving extirpation of the liver concluded that the organ is best prepared to meet stress when its stores of both protein and carbohydrate are ample. Similar conclusions were drawn by others, notably Messinger and Hawkins,[53] who demonstrated that protein is most effective in protecting dogs against injury to the liver from arsphenamine, and by Ravdin and his associates,[54] who saw best protection for the liver against the stress of operation when at least 20 per cent of the calories of the diet were derived from protein. Clinical application was made of this by Patek and Post,[55] who accomplished results definitely beyond expectation in their patients with cirrhosis of the liver by giving them diets of 2,900 to 3,000 calories in which was included 116 to 135 Gm. of protein. More recently, Morrison[56] reported like results in cirrhosis with a diet that provided 200 to 300 Gm. of protein daily. The regimen devised for patients with cirrhosis at the Hospital of the Rockefeller Institute for Medical Research[57] included diets high in protein and rich in carbohydrate, but the excellent results accomplished in that hospital were credited largely to the appetite-restoring effects of crude liver extract. In a disease that formerly was regarded as invariably fatal, this high protein, low fat regimen, which includes also the administration of large quantities of vitamins and crude liver extract, is accomplishing unexpectedly happy results.

A similar diet is now used in treatment of infectious hepatitis. Capps and Barker[58] gave their patients with this disease 200 Gm. of protein daily, and Berger[59] described in detail a diet of 3,500 calories successfully used in the Mediterranean Theater of Operations which provided 225 Gm. of protein. This is a great deal of food to offer a patient, but with good nursing he can be induced to take it. What would the physician of thirty years ago have thought of prescribing 225 Gm. of protein daily for a jaundiced man with high grade fever and a large, tender liver? He would have stood aghast, but the general adoption of this regimen gives testimony to the high value placed on protein today.

CONCLUSION

I should like to conclude with a question. The protein quota of the American soldier's ration in the second World War was liberal—more liberal than that of any other soldier in the world—not the 70 Gm. of today's recommended daily allowance, or the 100 Gm. of Lusk, or the 120 Gm. of Atwater—but 140 Gm., and he ate it all. Measured in terms of greater vigor, quicker and more assured recovery from injury and a higher degree of morale, did this liberality of protein allowance in the American soldier's ration contribute to the winning of the war? I believe it did.

USE OF STREPTOMYCIN IN SURGICAL PATIENTS

EDWARD J. BEATTIE Jr., M.D.
and
BRIAN BLADES, M.D.
Washington, D. C.

Since the discovery of streptomycin by Waksman[1] (in 1944) data have been obtained which show the value of this drug as an adjunct to the surgical treatment of pulmonary tuberculosis. The demonstration that streptomycin had a beneficial effect on tuberculosis in the guinea pig by Feldman[2] and the report that this drug seemed to improve patients with pulmonary tuberculosis by Hinshaw[3] in 1946 have been followed by other studies concerning the value of streptomycin in pulmonary tuberculosis.

The largest number of cases in which pulmonary tuberculosis treated with streptomycin was evaluated has been collected under the auspices of the Veterans Administration.[4] (Over 3,000 patients with various types of tuberculosis have been treated.) It was found that those patients in whom a beneficial effect was obtained showed clinical response within the first two weeks of therapy. Approximately 60 per cent became afebrile after the administration of streptomycin. It was also found that this agent had little if any beneficial effect or [illegible] us tuberculous lesions or caseous [illegible] of tuberculous pulmonary cavities was variable. Good results were obtained in improving exudative forms of disease while the drug was administered.

The concept of appropriate dosage of streptomycin has been changed.[4c] The present feeling is that as good response can be obtained with 1.0 Gm. of streptomycin given in two doses daily as with the higher doses. One-half gram per day in one dose is probably just as effective as the 1 Gm. a day dose, but not enough data

have yet been accumulated to permit one to be certain of this fact.

In the Veterans Administration study an arbitrary duration of treatment was chosen. The patients who were to be treated surgically for pulmonary lesions were given streptomycin seven days prior to and for fourteen days after operation. It is possible that shorter courses than this may be effective, but more data will be needed.

The toxic complications are greater with the higher dose.[4c] With 1 Gm. per day there has been a decided reduction in the toxic manifestations. The 0.5 Gm. per day dose has practically no toxic effects. The toxic symptoms are apparently related to the level of streptomycin in the blood. It is interesting that 1.0 Gm. of streptomycin given in five doses a day has a higher rate of toxic complication than does 1.0 Gm. in two doses per day. It would seem from this that the sustained blood level of streptomycin per se is more toxic than an inconstant level.

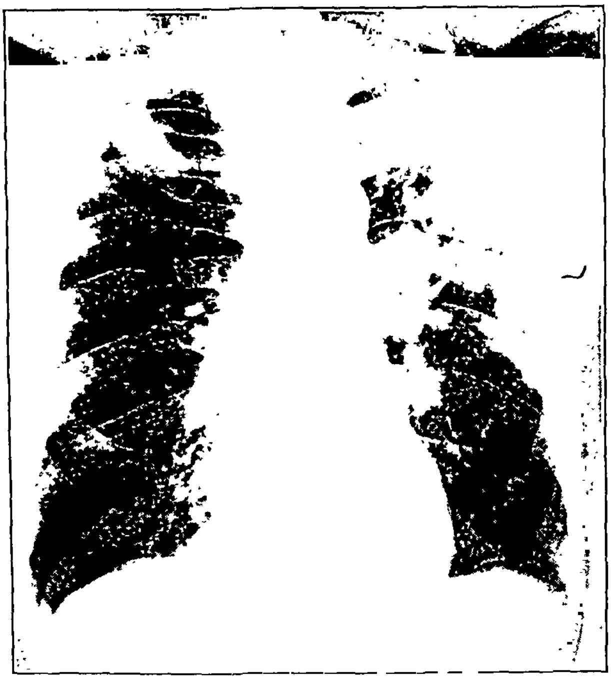

Fig. 1.—Roentgenogram of the chest of a 55 year old Negro man with tuberculosis of the left lung.

Studies have been carried out to learn the absorption rate of streptomycin from the pleural cavity and to learn the pathologic effect of streptomycin on the pleural serosa.[5] It was found that 0.5 Gm. of streptomycin in one dose in the pleural cavity of the dog did not produce any detectable harmful pathologic effects in pleura examined seven days after administration of the streptomycin. It was also found that 0.5 Gm. of streptomycin placed in the pleural cavity of the patient at the time of open thoracotomy produced high blood levels of streptomycin, which were reached rapidly. There were no apparent differences between decidedly scarred and unscarred pleuras. Levels as high as 25 micrograms per cubic centimeter were reached in thirty minutes, which fell gradually during the course of the next four hours and at the end of eight hours had fallen to approximately 1 to 2 micrograms per cubic centimeter.

Studies[4c] concerning the resistance of the tubercle bacilli have demonstrated that in vitro nearly all tubercle bacilli will not grow in 10 micrograms per cubic centimeter of streptomycin. Most tubercle bacilli will stop growing in only 1 microgram per cubic centimeter. However, after one hundred and twenty days of treatment with streptomycin it has been found that 70 per cent of tubercle bacilli will grow in 10 micrograms

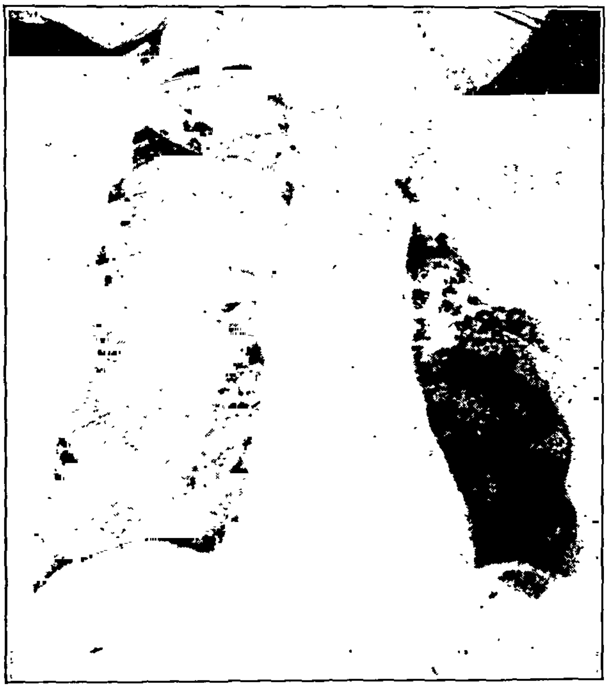

Fig. 2.—Roentgenogram of the chest after three stages of thoracoplasty had been carried out on the patient seen in figure 1. The thoracoplasty was a failure in that the sputum was still positive and tuberculous bronchiectasis in the lower lobe could be demonstrated by a bronchogram.

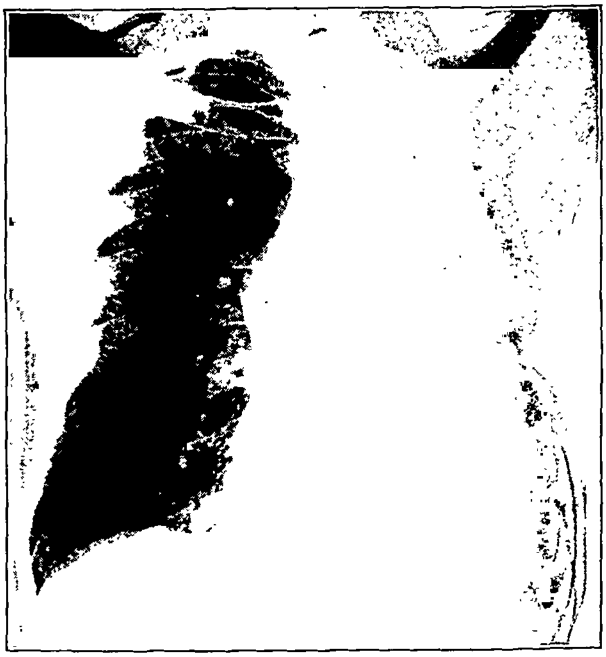

Fig. 3.—A roentgenogram of the chest taken after a left pneumonectomy had been performed on the patient pictured in figures 1 and 2. The patient is now afebrile, asymptomatic and gaining weight.

---

per cubic centimeter of streptomycin, that the majority of tubercle bacilli will grow in over 100 micrograms per cubic centimeter and many will grow in over 1,000 micrograms per cubic centimeter. The length of time that it takes for a tubercle bacillus to develop resistance[6] is variable. Apparently it can develop in as little as six weeks.

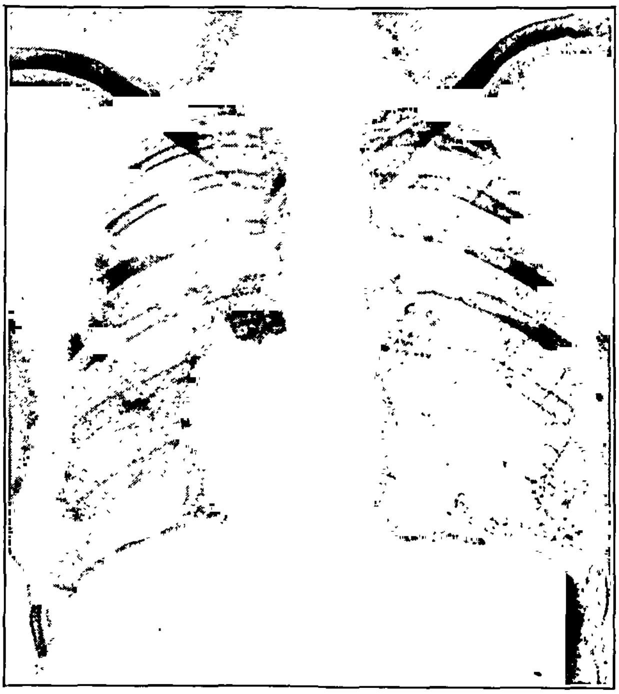

Fig. 4.—Roentgenogram of the chest of a 30 year old white housewife with tuberculous tension cavity in the upper lobe of the left lung. The patient was very sick with a high temperature.

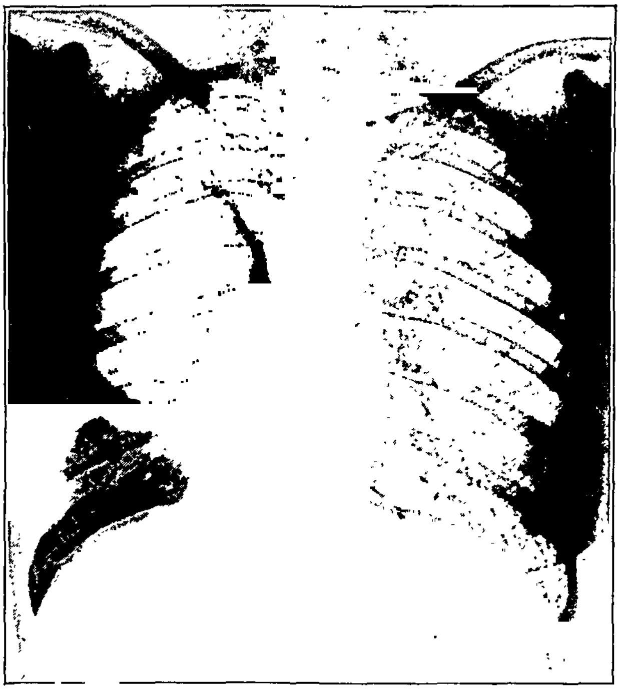

Fig. 5.—Roentgenogram of the patient shown in figure 4. She was treated with streptomycin. The cavity had diminished in size, and she had only a low grade fever at this point.

Prior to the use of streptomycin as an adjunct in pulmonary resection for pulmonary tuberculosis there were 600 cases of resection reported in the American literature since 1933.[7] Of these 600 cases resection was done in 520 after 1942. In this series the total operative mortality rate was 25 per cent. The operation in 12 per cent of the cases was followed by empyema and in 8 per cent by complicating bronchopleural fistulas. Reports of large series of thoracoplasties prior to the use of streptomycin had shown a rate of spread or reactivation of the tuberculosis of approximately 3 to 6 per cent.[7] Empyema following thoracoplasty was rare. Overholt[8] reported that in 104 cases of pulmonary resection without streptomycin for tuberculosis between March 31, 1944 and April 5, 1946, there were 16 deaths, a 15 per cent mortality rate.

The Veterans Administration[7] conducted a study of the value of streptomycin protection for thoracoplasty. In this they had a control series of 249 patients who underwent 648 thoracoplasties. There were 36 cases of tuberculous spread or reactivation (5.6 per cent) and 16 cases of wound infection (2.4 per cent). There were 258 cases in which there were 699 thoracoplasties protected with streptomycin. There were 14 cases of tuberculous spread or reactivation (2 per cent) and 8 cases of wound infection (1.1 per cent). This seems statistically significant, but in a breakdown of the figures from the various clinics it seems probable that there is not a significant difference.

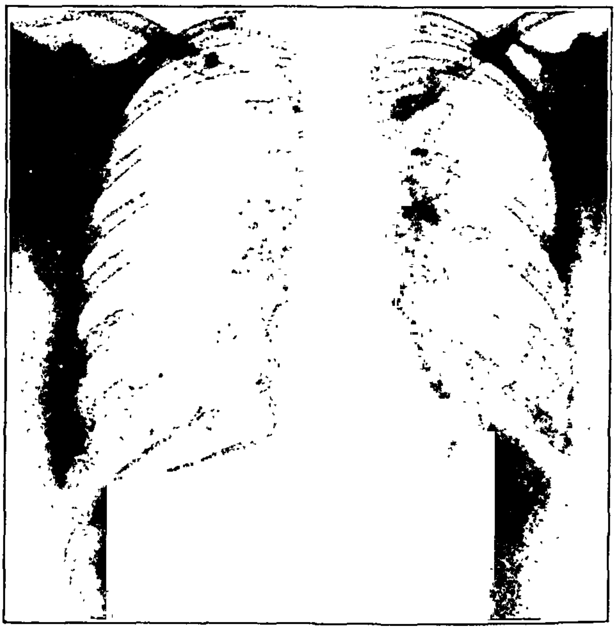

Fig. 6.—This is a film taken post-operatively on the patient shown in figures 4 and 5. The upper lobe of the left lung was removed.

Various authors have reported decidedly beneficial effects of streptomycin in pulmonary resections for tuberculosis. The Veterans Administration[7] reported that in 129 cases of pulmonary resection there have been 5 operative deaths and 1 postoperative death (4.5 per cent mortality rate). There have been 4 cases of tuberculous spread in this series, 8 cases of complicating bronchopleural fistulas, 5 cases of empyema and

6 cases of infection. Moore,[9] in reporting 70 cases of resection in which streptomycin was used, reported 7 per cent operative mortality with 3 per cent tuberculous spreads, 3 per cent complicating bronchopleural fistulas, 2 per cent empyemas and no wound infections. Bailey,[10] in contrasting results in 100 cases of pulmonary resection without streptomycin and those in 100 cases of pulmonary resection with streptomycin, reported that in the 100 of the control series there was a 25 per cent operative mortality rate, 18 per cent tuberculous spread, 8 per cent complicating bronchopleural fistulas and 11 per cent empyemas, whereas in the 100 cases in which streptomycin was used there was an operative mortality rate of 14 per cent with only 1 per cent tuberculous spread, 1 per cent complicating bronchopleural fistulas and 2 per cent empyemas. The Veterans Administration series showing a 4.5 per cent operative mortality rate, in contrast with the reported cases prior to the use of streptomycin with a 25 per cent mortality rate, is striking.

We had a relatively small series of desperate risk patients in whom pulmonary resections and thoracoplasties have been carried out with streptomycin protection. Until June 15, 1948, 15 patients had been operated on who had had 38 thoracoplasties. There were 14 consecutive patients who had pulmonary resections; there were 9 patients who had open pneumonolyses. The dosage of streptomycin used in these cases has changed as more knowledge about the dosage of streptomycin has been obtained. The patients with recent resection received 1.0 Gm. of streptomycin per day in two divided doses for one week prior to operation and two to three weeks following operation. At the time of operation they also received 0.5 Gm. of streptomycin into the pleural cavity. Some of the patients with thoracoplasty received 1.0 Gm. in two doses for one week prior to and two weeks after thoracoplasty, but a considerable number received 0.5 Gm. for one day prior to and four days following operation. All patients have received penicillin in addition to the streptomycin. In this series there have been no deaths and no postoperative spreads. There were 2 cases in which there was a serious impairment of hearing resulting from prolonged courses of streptomycin (2.0 Gm. per day) given in outside sanatoriums. Another patient, operated on too recently to be included in the report, came to us as a desperate risk for resection, having already received enough streptomycin in an outside hospital to make her tubercle bacilli resistant to streptomycin. In spite of combined streptomycin and para-aminosalicylic acid therapy, it seems as if she may have a contralateral tuberculous spread.

This is a small series in which the numbers are not statistically significant, but when one considers the desperate nature of these cases it is probably an important commentary on the value of streptomycin that none of these patients have died or had serious complications. Without streptomycin it could certainly be expected that serious complications should have arisen. The accompanying roentgenograms illustrate results in 2 cases in which pulmonary resections were carried out.

COMMENT

According to the American literature 600 cases of resections for pulmonary tuberculosis have been reported since 1933 without the use of streptomycin. In these cases there has been a 25 per cent operative mortality rate, with 12 per cent empyemas and 8 per cent complicating bronchopleural fistulas. In thoracoplasty for pulmonary tuberculosis a 3 to 6 per cent rate of tuberculous spread with rare empyemas can be expected. In using streptomycin the Veterans Administration reported that in 129 cases they had a 4.5 per cent operative mortality rate. Others have shown comparable reductions in operative mortality. Analyses of 3,000 cases in which streptomycin was used in the Veterans Administration series revealed that 1.0 Gm. in two divided doses per day is probably the optimum dose. Streptomycin therapy should be started seven days prior to and continued for fourteen days after operation. The toxic effects are nearly eliminated with this dosage. Pleural absorption of streptomycin is rapid, and high levels are reached in one hour. Resistance of the tubercle bacillus to streptomycin develops promptly. The exact time is not known, but the bacilli may become resistant in forty days. In a small series reported here, of 38 thoracoplasties, 14 resections and 9 open pneumonolyses, there have been no deaths and no spreads.

Sweet[11] reported a follow-up study of 27 patients with lobectomy and 36 with pneumonectomy at least one year following operation. Of the 27 patients with lobectomy 2 died postoperatively, 5 died of tuberculosis, 7 were alive with positive sputum and 13 were well with normal sputum. Of the 36 patients with pneumonectomy 7 died postoperatively, 7 died later of disease, 5 were alive with positive sputum, 1 was clinically well with positive sputum and 16 were well with normal sputum.

We have followed a policy of doing phrenic nerve crushes for lower lobe lobectomies, partial thoracoplasties for upper lobe lobectomies and thoracoplasties following pneumonectomies in patients who had not had collapse measures carried out prior to resection.

The elapsed time postoperatively has not been long enough to permit analysis of the postoperative condition of the patients in our series.

With the added protection which streptomycin affords pulmonary resection for tuberculosis it is technically possible to carry out major resection in desperate risk patients. However, one must be cautious in removing large amounts of lung tissue. We have already seen evidence that the pulmonary reserve in these patients may be inadequate for normal living, even though the tuberculosis is eradicated.

CONCLUSION

Streptomycin is a valuable adjunct in the surgical treatment of pulmonary tuberculosis. The immediate complications are decidedly reduced. Not enough time has yet elapsed to determine that the long range survival rate will be better in the patients treated with streptomycin than in those undergoing resection for pulmonary tuberculosis prior to the use of streptomycin.

In a series of desperate risk cases of pulmonary tuberculosis treated surgically there have been no deaths and no spreads. The fact that resistance of the tubercle bacillus to streptomycin develops in as little as six weeks makes it important that streptomycin be reserved for surgical treatment in any cases which may potentially be surgical. It should not be used in the cases of minimal pulmonary tuberculosis.

ABSTRACT OF DISCUSSION

Dr. Emil Bogen, Olive View, Calif.: No doubt the administration of streptomycin prior to operation may lead to regression of soft exudative, components of lesions and decided reduction in sputum volume and bacillary content, but for such preparation it would generally be expected that treatment for more than a few days to a week before operation should be given to obtain the maximum effect in this direction. If streptomycin were actually bactericidal, its administration at the time of operation might be of value, but, since my own experiments and those of many others indicate that its effect is purely to retard multiplication of the bacilli and that it does not kill them, this local or simultaneous administration may give the surgeon undue confidence in a futile effort. Similarly, streptomycin administered after operation is extremely effective in the treatment of any spreads or reactivation which may have occurred as a result of aspiration, dissemination or trauma during the operation. If such spreads occur it would scarcely seem adequate to treat them for only a week or two following their production. It would seem wiser, therefore, for surgeons to withhold streptomycin during and for a short time following the operation, until evidence of spread or infection of the chest has actually been observed, whereupon adequate treatment for at least a month, or six weeks, might better be expected to care for such complications. Otherwise, patients may show spreads after cessation (two weeks after resection) of the usual so-called protective regimen. I wish to ask Dr. Beattie and Dr. Overholt whether in their experience spreads are not more apt to occur after the second rather than the first stage of thoracoplasty and whether delayed spreads, some months after resections, are not more to be feared than immediate spreads at the time of operation. If this is generally true, would it not be wise to retain sensitivity to streptomycin on the part of the tubercle bacilli remaining in the chest by withholding the treatment until such complications have developed? Administering streptomycin for an illusory protection before and at the time of operation may result in the development of resistant forms of tubercle bacilli which may prove refractory to treatment administered at a later time when it might be more logically expected to be of value. Streptomycin is a wonderful agent for the preparation of tuberculous patients for surgical treatment of the chest, making possible operations on many patients who would otherwise not be able to receive such treatment and greatly lessening the dangers of the operation. It is also a valuable agent for the treatment of any spreads or reactivations which may occur as a result of operation.

Dr. Richard H. Overholt, Boston: I am inclined to agree that the word protection is not the right one to use in this connection. Each surgeon is interested in conducting all patients through the operation as safely as possible. He is balancing risks. There are certain hazards in anything he does, and there is also a hazard in the disease. If it is possible to prepare a patient by various methods so that the risk of operation will be reduced, then, of course, those methods should be used.

Dr. Edward J. Beattie, Washington, D. C.: In reply to questions that were brought up, the Veterans Administration study was carried out to see whether streptomycin is really necessary in patients who are to have thoracoplasty. At present we do not seem to have enough information to warrant the use of streptomycin in the ordinary case, but there is also the problem of whether thoracoplasty cannot be done in cases in which the operation previously had been refused because the disease was too acute or the patient was too febrile at the time. As regards the duration of treatment, we feel that, if the decision is made to use streptomycin during the course of the thoracoplasty, in as much as resistance seems to develop in most cases in one hundred and twenty days and in many cases in six weeks, it is necessary to use an elapsed time so that all the thoracoplasty can be carried out while the tubercle bacillus is still sensitive to streptomycin. Since thoracoplasty takes in about four to six weeks, that is the determining factor. The Veterans Administration has proved that there is little doubt that streptomycin cuts down the incidence of postoperative complications, which has been high in most of the previous reports. As regards the long term follow-up, what will happen later in the cases of resection in which there has been preparation with streptomycin, we are not prepared to say. It will take a longer time to follow up these cases.

DIAGNOSIS AND TREATMENT OF INDUSTRIAL SOLVENT POISONING

REX H. WILSON, M.D.
Akron, Ohio

Many different kinds of solvents are used in industry today. Some of these are rather toxic. Every practicing physician is liable to encounter patients who are suffering from the effects of overexposure to these solvents. It is well, therefore, to become aware of their toxic properties and to review the symptoms and treatment of overexposure to them.

The common solvents can be classified into groups. These include the aromatic hydrocarbons, the chlorinated hydrocarbons, petroleum distillates, ketones, esters, alcohols and carbon disulfide. The toxicity of these compounds varies considerably. It is impossible to discuss here all of the various members of these groups; consequently, for the sake of brevity, representative members will be discussed.

AROMATIC HYDROCARBONS

Representative of the aromatic hydrocarbons is benzene. It is considered to be one of the most dangerous of the industrial solvents. It can be absorbed by the respiratory tract, the alimentary tract and probably the skin.

Cases of poisoning in human beings have been found with exposure to atmospheric concentrations as low as 25 parts per million. Concentrations of 50 to 100 parts per million are considered to be safe for the average person. Individual susceptibility varies. Acute benzol poisoning is rare. The symptoms of acute poisoning are referable to the central nervous system. There are muscular tremors, salivation, violent twitching, exhaustion, narcosis, paralysis, convulsions and death from paralysis of the respiratory center.

Patients exposed to concentrations of vapors between 50 to 500 parts per million, with the average concentration being about 100 parts per million, show symptoms of lassitude, malaise, nausea, vomiting, dizziness and headaches. Macular dermatitis may appear. As exposure continues symptoms become more severe. Hemorrhages under the skin and from the body cavities may occur. Ecchymosis and petechiae may be the first symptoms noted. Diplopia, especially for close distances, occurs in some cases. If the person is highly susceptible, or if the exposure has been great and prolonged, he may get physiologic or functional depression of the bone marrow. This varies in degree from a slight hemopoietic suppression to a total bone marrow aplasia.

The symptoms of a total aplasia are usually those of benzol absorption followed by prostration. On the other hand, it is sometimes strange how well the patient may appear. Aside from fatigue there may be no other complaints.

Read in a Joint Meeting of the Section on General Practice and the Section on Preventive and Industrial Medicine and Public Health at the Ninety-Seventh Annual Session of the American Medical Association, Chicago, June 23, 1948.

The best index of benzol absorption is the blood cell count. All components of the blood are affected, being lowered. Most important, the total leukocyte count falls. Special reference should be made to the differential count. The ratio of polymorphonuclear cells to monocytes is changed. The number of monocytes increases and the polymorphonuclear cells decrease. The red blood cell count is lowered. The hemoglobin usually falls. It has been reported by some investigators that the leukocyte count may be elevated at first. However, when this occurs it is quickly followed by a general lowering of the count. The platelet count is lowered, dropping to practically zero in cases of severe disease. The reticulocyte count is also lowered. The prothrombin time is normal. The red blood cells exhibit anisocytosis, poikilocytosis and polychromatophilia. In all patients showing a decided blood reduction a bone marrow biopsy should be done. The degree of aplasia can be determined, and usually an accurate prognosis can be made. Patients with total aplasia usually die. Patients with partial aplasia have a prognosis dependent on the amount of regeneration present. Results of urinalysis are usually negative. The blood pressure may be lowered.

Aplastic anemia is to be differentiated from granulocytopenia and acute leukemia. The symptoms of all of these diseases are very similar. In granulocytopenia the red blood cell and platelet counts are usually essentially normal. In acute leukemia the white blood cell count may be normal, raised or lowered, with the differential count showing a decided increase in very young white blood cells. The liver and spleen are usually enlarged in acute leukemia and are normal in aplastic anemia and granulocytopenia. Sore throat is common in leukemia and especially so in granulocytopenia. It must be recognized that the differential diagnosis in these three diseases may be difficult. Bone marrow studies usually reveal the proper diagnosis.

In patients with mild benzene intoxication, with or without a change in the blood cell count, the treatment is permanent removal from exposure. These patients will return to normal in a few days with no medication.

In patients in whom absorption is sufficient to cause a decided change in the blood picture more active treatment is necessary. These patients are given absolute bed rest. Multiple small whole blood transfusions (about 250 cc.) are given as often as once daily. When severe reactions occur, blood plasma may be used in place of whole blood.

Direct bone marrow transfusions may be given as often as twice weekly. In this procedure 2 to 5 cc. of bone marrow are removed from the sternum of a compatible donor and introduced directly into the sternum of the patient. From the same donor 250 cc. of blood are drawn and transfused into the patient. This is followed by 1,000 cc. of isotonic sodium chloride solution.

Large daily doses of liver, iron, calcium, phosphorus, yellow bone marrow and multiple vitamins are given. A full diet is prescribed. The patient's general hygiene is improved as much as possible. Bleeding areas are stopped if at all possible. Pentnucleotide® (the sodium salts of the pentose nucleotides from the ribonucleic acid of yeast) has been used and found to be effective in some cases.

The poor resistance in these patients is due to the lowered leukocyte count. Secondary infection, the commonest of which is a Vincent's organism infection of the mouth, is one of the causes of death. For certain types of severe secondary infection, the antibiotics are indicated.

The response to therapy is slow, since a considerable time is necessary for the bone marrow to regenerate. Splenectomy may be considered in some cases of refractory disease. Any treatment at best is not wholly satisfactory. Extreme caution must be observed in the handling of this chemical. In too many patients overexposure proves fatal.

Atmospheric concentrations should not exceed 100 parts per million. Skin contact with benzene should be avoided. Blood cell counts, including hemoglobin, red and white cell, and differential determinations should be made for all exposed persons at least every two months. Sternal bone marrow examinations should be done in suspicious cases. Persons with blood or bone marrow abnormalities should be considered for immediate and permanent transfer away from these solvents. Wherever possible an attempt should be made to substitute less toxic solvents.

CHLORINATED HYDROCARBONS

Probably the most commonly used member of the chlorinated hydrocarbon group is carbon tetrachloride.

The symptoms of overexposure to the chlorinated hydrocarbons usually start with a feeling of drowsiness, which, if exposure continues, is accompanied with anorexia, nausea, vomiting, abdominal pain, diarrhea, headache and dizziness. Jaundice may develop. Oliguria progressing into anuria may also develop. In some the occurrence of bronchitis or bronchial pneumonia has been reported. Some persons present hypertension. A constriction of the visual color fields has also been noted. Polyneuritis has been described. The mode of action is that of a narcotic with direct or indirect effects on the central nervous system. The chlorinated hydrocarbons also act as hepatotoxics, probably causing cirrhosis of the liver. This is especially noted when the diet has been deficient in calcium or there has been a depletion of body protein. The kidneys appear to be primarily involved in acute intoxications, the lesion being described as destruction of the epithelium with the stroma left intact. Hypertension and azotemia may accompany the kidney involvement. Acute exposure to the chlorinated hydrocarbons is usually manifested by narcotic intoxication, with liver and renal damage in six to twenty-four hours. The symptoms of chronic poisoning usually simulate those of portal cirrhosis.

A careful evaluation of the patient should be made, including tests of hepatic function, tests of renal function, electrocardiogram and roentgenogram of the chest. Dextrose should be given intravenously, either in isotonic sodium chloride solution or distilled water. A high carbohydrate–high protein diet with a normal fat content is recommended. Methionine and choline have been reported to be of benefit. The patient should be kept under observation until all signs of hepatic and renal damage have disappeared or have become nonprogressive.

Workers should be carefully selected. Obese and undernourished persons, nephritic and diabetic persons, those with pulmonary and hepatic disease and those having an enlarged thymus or thyroid should be rejected. Frequent physical inspections of exposed persons should be made, particular attention being paid to renal and hepatic function. Atmospheric concentrations should not exceed 100 parts per million. Skin contact should be avoided.

KETONES

The common ketones used in industry are acetone and methyl ethyl ketone. In my experience no cases of occupational disease have been attributed to the ketones. A narcotic action has been attributed to acetone when given to animals. It is known that when persons are exposed to moderate concentrations of acetone, it may be found in the urine without clinical symptoms being noted. It is wise to suspect that the ketones have a narcotic action and may cause a depression of the body temperature, respirations and heart rate. Exposure to excessive atmospheric concentrations of most of the ketones results in severe optic and respiratory irritation. Treatment is entirely symptomatic.

Personal comfort is the determining factor as to the tolerable atmospheric concentration. Skin contact should be avoided.

The esters commonly used are methyl acetate, ethyl acetate, isopropyl acetate and butyl acetate. Some of the esters have an irritating action on the respiratory passages. They are also irritating to the eyes and may cause slight narcosis. In general the acetates are considered to be among the safest of the solvents. No cases have ever been reported of genuine acetate poisoning. Treatment is entirely symptomatic.

Since these chemicals are not considered severely toxic, in most cases the maximum allowable concentrations are based on comfort requirements. Skin contact may result in dermatitis and should therefore be avoided.

ALCOHOLS

The most toxic of all of the alcohols is methyl alcohol. Methyl alcohol is a source of grave injury to many industrial workers. It has a specific action on the optic nerve, and with long enough exposure blindness may result. The action is that of inflammation of the optic nerve followed by atrophy. A considerable amount of methyl alcohol poisoning was noted during prohibition days when wood alcohol was used in large amounts with subsequent optic nerve degeneration and blindness. The other alcohols, because of their volatility, are not considered to be especially dangerous. Cases of narcotic poisoning have been attributed to them. The higher alcohols, like butyl and amyl, have an irritant action as well as some poisonous action on the protoplasm.

If methyl alcohol is taken internally, the use of an emetic is indicated. Four per cent sodium bicarbonate solution, as a gastric lavage, is excellent. When the toxic action results from absorption through the skin, a lavage is of no benefit. Because acidosis due to the formation in the system of formic acid results, sodium bicarbonate or sodium lactate given orally or intravenously is advisable. This treatment should be continued until the acidosis has been corrected. The patient should be kept warm and symptomatic treatment offered. With the exception of the eyes, most abnormalities from chronic exposure clear up after cessation of exposure. The treatment of exposure to the other alcohols is entirely symptomatic.

As with all solvents, prolonged skin contact should be avoided. This is especially true of methyl alcohol, which can be absorbed through the skin in sufficient quantities to be harmful. Physical examinations of personnel exposed to methyl alcohol should be made at two to three month intervals. This should include an ophthalmologic examination. Atmospheric concentrations of methyl alcohol should not exceed 200 parts per million.

PETROLEUM DISTILLATES

Probably the best known of the petroleum distillates is gasoline. These distillates are narcotics, and it is possible to produce complete anesthesia with heavy doses. However, their anesthetic properties are much less than those of the aromatic and chlorinated hydrocarbons. For this reason they may be more desirable for commercial use.

The susceptibility of human beings varies greatly. Acute poisoning produces the symptoms of a narcotic. There is fulness of the head, headache, blurred vision, dizziness, unsteady gait and nausea. The patient becomes irritable. Burning of the eyes and dimness of vision are common complaints. It is of interest to note that on exposure to air the symptoms become aggravated at first. Massive exposures may cause sudden collapse, coma and death. In fatal cases there is usually some blood vessel damage, with small hemorrhages into the body organs. Bronchitis, pulmonary edema and cellular damage of the kidneys, liver and the spleen have been described. The symptoms of chronic poisoning are usually central nervous system in origin. Epileptiform seizures, unconsciousness, tonic muscular spasms, lancinating pains in the limbs, coldness and numbness in the hands, loss of strength, loss of memory, drowsiness, dimness of vision, confusion and dulness of mentality and tremors have all been described.

Degeneration of the pyramidal tracts has been described. The effect of chronic petroleum distillate poisoning on the blood is a matter of controversy. It is usually felt that the effect of gasoline fumes on the blood differs from that of benzene only in degree. It must also be mentioned that certain petroleum distillates are suspected of containing carcinogenic substances. At the present time considerable research is being performed along this line.

The treatment of acute petroleum distillate poisoning should be directed toward the prevention of respiratory and circulatory collapse. After intense exposures pulmonary edema usually occurs. Oxygen therapy, preferably with a face mask and positive pressure, is indicated. Saturated clothing should be removed. Circulatory and respiratory stimulants may be necessary. Bronchopneumonia may develop. Treatment with the antibiotics may then be necessary. Most of the patients are rather nervous and restless. Sedation may be indicated. Conjunctivitis may be treated by dropping 1 : 1,000 epinephrine solution into the eyes four times daily, followed by cold applications. Boric acid ophthalmic ointment may also be used. Iron medication should be given if anemia develops.

The maximum allowable concentrations of gasoline have been stated to vary from 100 to 1,000 parts per million. These solvents are not considered to be severely toxic, and in most cases the values are based more on personal comfort than on toxic requirements. Skin contact should be avoided.

CARBON DISULFIDE

Carbon disulfide has long been recognized as an industrial poison. The commonest symptom is neuritis, which may affect any of the nerves and most commonly involves the nerves of the limbs and certain of the cranial nerves. Both the motor and the sensory nerve fibers are affected, causing abnormal sensations and loss of power. This is an insidious type of poisoning in which permanent damage to the brain may result. The mental symptoms may be exhibited in varying degrees, ranging from simple irritability and depression to manic depressive insanity.

There is no specific treatment for chronic carbon disulfide poisoning. A diet high in vitamin content with an adjunct of vitamin B complex may be of value. Liver extract may be given. It is very important that necessary precautions be taken to avoid overexposure to this compound. Atmospheric concentrations should not exceed 20 parts per million. Skin contact must be avoided. Periodic physical examinations which include a careful examination of neurologic symptoms should be made at monthly intervals on all persons handling the compound. Removal from contact with it is imperative at the first intimation of any unusual symptoms. The drinking of alcoholic beverages by exposed personnel should be discouraged.

THE PNEUMONOCONIOSES

Which Industrial Dusts Are Inert? Which Are Harmful? Why?

L. E. HAMLIN, M.D.
Chicago

The term pneumonoconiosis has been so loosely applied to industrial pulmonary conditions that some clarification appears to be desirable. It is an all-inclusive caption for a variety of pulmonary affections resulting from the inhalation of inert or harmful dust. Generically it does not imply fibrosis but simply "dust in the lungs." If one is to accept this meaning, therefore, pneumonoconiosis must include any retention of dust in the lungs, whether of industrial origin or not and whether of toxic, irritant, proliferative or inert dust. It must also include the anthracotic pigmentation from dust, carbon and smoke which all normal lungs exhibit; in the interpretation of pathologic change, the matter of degree as well as specificity must be considered.

From a practical standpoint, however, pneumonoconiosis refers mainly to pulmonary alterations attributable to those dusts encountered in industry which can cause proliferative reactions, roentgenologic patterns due to radiopaque properties or simple exaggeration of normal linear markings. These changes are entirely distinct from the action of toxic dusts, such as lead or mercury, for which the lungs act merely as the point of entry into the body. They differ also from the reactions produced by mycotic and other organic dusts, as will be explained.

Industrial dusts are listed by Kronenberg and Morse[1] as follows:

I. Organic Dusts:
  A. *Nonliving:*
    1. Toxic and/or irritant
  B. Living:
    1. Bacterial
    2. Fungous
II. Inorganic Dusts:
  A. Toxic and/or irritant
  B. Fibrosis-producing
  C. Nonfibrosis-producing

Classification of industrial dusts into "harmful" and "inert" categories is not easy because some which are usually considered innocuous may produce definite pathologic changes under certain conditions, such as prolonged excessive exposure. In the following modification of Sander's[2] grouping, certain dusts are designated as harmful even though they do not produce fibrotic pulmonary alterations.

Organic dusts arise mainly from animal or vegetable materials, but many are synthetic. They do not cause pulmonary fibrosis but are capable of producing local irritation which results in such things as dermatitis, dental lesions, irritation of the mucous membranes and conjunctivitis. Sappington[3] has listed more than one hundred occupations in which these symptoms and/or allergic manifestations may be produced from substances like pollens, horse hair, furs, wool and wood dust.

Byssinosis, an occupational condition resulting from dust encountered in the cotton industry, has been reported in Europe as a definite occupational disease, but its existence as a clinical entity in this country is questionable. Acute symptoms and roentgenologic findings suggestive of pneumonia of the influenzal type have followed exposure to an organic dust produced by crushing or shredding bagasse, a waste product of sugar cane. The condition is described as bagassosis and, like byssinosis, may be due to an allergic reaction rather than to actual pathogenic properties of the dust itself. There is also some recent evidence to show that bagassosis may be caused by a fungus or possibly by bacteria attached to the dust and that the dust itself is relatively innocuous.[4] C. F. Long[5] investigated more than 1,247 workers in the tobacco industry and concluded that tabacosis does not develop in the lungs of those who inhale tobacco dust. Recent studies, however, by McCormick, Smith and Marsh[6] indicated that there may be a significant free silica hazard in the stemming and redrying operations in that industry.

Pulmonary diseases caused by fungous infections have been receiving more attention in recent years. Increasing recognition of these cases has led many observers to believe that they may be more prevalent than is generally supposed. Mycotic diseases are usually nonindustrial and are found only in certain geographic locations. Nevertheless some cases have been attributed to occupational exposure. In 1945 Coe[7] reported a case of bronchopulmonary aspergillosis, occurring in an employee of the Chicago Stock Yards, for which an award of compensation was granted and upheld by the Industrial Commission of Illinois.

Fungi are filamentous plants of simple structure, among them being various yeasts and molds. They may attack the lungs or other parts of the body and

give rise to such conditions as moniliasis, aspergillosis, sporotrichosis and coccidioidomycosis. It is important for one to bear this fact in mind, particularly when reviewing the industrial roentgenogram of the chest. The pulmonary shadows produced by yeasts and molds may easily be confused with those caused by free silica unless careful consideration is given to the patient's occupational history and exposure to dust.

In recent years considerable research has been done on multiple pulmonary calcification. This condition has been commonly observed in roentgenograms of the chest of persons living in the south, central and eastern states. It has been described under such names as miliary calcification, calcicosis and "wheatena." The origin of the small, widely scattered, sharply defined calcified nodules was obscure until a short time ago, but it now seems reasonably certain that they are caused by the fungus Histoplasma capsulatum. Histoplasmosis has usually been considered a fatal disease, but it now appears that there may be a benign form which is asymptomatic, nondisabling and evident only by the characteristic roentgenologic appearance. It is not clinically significant, and there should be no difficulty in distinguishing the condition from silicosis or other occupational diseases manifested roentgenologically.

Table 1.—*Industrial Dusts*

Harmful or Potentially Harmful		Inert	
Substance	Type of Effect	Substance	Type of Effect
I. Organic			
A. Animal	Allergic		
Dander			
Fur			
Hair,			
Etc.			
B. Vegetable	Allergic or infectious pneumonitis		
Pollens			
Grains			
Cotton (byssinosis)			
Sugar cane (bagassosis)			
Tobacco (tabacosis)			
C. Bacteriae			
D. Fungus			
Aspergillosis			
Coccidioidomycosis	Irritant		
Blastomycosis	Fibrogenic		
Sporotrichosis	Allergic		
Geotrichosis	(Occasionally occupational)		
Moniliasis			
Histoplasmosis			
II. Inorganic			
A. Metallic			
Chrome and its compounds	Irritant, causing local irritation of upper respiratory tract	Carbon (Anthracosis)	Roentgenologic changes only
		Calcium (Calcicosis)	
		Iron (Siderosis)	
Cadmiun		Barium (Baritosis)	
Arsenic	May be toxic	Tin (Stannosis)	
Lead	Absorption and intoxication	Aluminum	
Manganeses		"Carborundum" (silicon carbide)*	
Mercury		Emery †	
Zinc		Aluminum oxide	
Beryllium	Pneumonitis		
Bauxite	Chronic granulomatosis (exact etiology undetermined)		
B. Free Silica (silicon dioxide)			
C. Silicates		Talc, mica, soapstone, feldspar, etc.	(Few cases reported; e. g., talc "pneumonoconiosis," probably due to quartz impurities)
Asbestos (Only silicate thought capable of producing fibrosis)	Asbestosis	Talc	
		Mica	
		Soapstone	
		Feldspar	
		Etc.	

* Carborundum does not exist in nature but is a manufactured product fused from sand, coke and sawdust.
† Emery is an aluminum oxide manufactured from bauxite. Corundum is natural aluminum oxide.

Certain of the inorganic dusts are primarily irritant, and their consequence is local inflammation of the upper respiratory tract. They are not proliferative but if inhaled in sufficient amounts may produce general poisoning. These include such substances as chromium and its compounds, cadmium and arsenic. While it is recognized that the great majority of industrial dusts are inert, as far as causing disabling fibrosis is concerned, one should not forget that certain other substances can produce dust or fumes which may cause serious illness. These are the heavy metals, such as lead, mercury and manganese. As pointed out earlier, dust or fumes from them do not cause structural lung changes but merely use the lungs as a portal of entry into the body. In later years serious toxic effects have been attributed to beryllium and its compounds and to fumes arising from the fusing of bauxite in the manufacture of artificial abrasives. These two conditions have resulted in severe pneumonitis with definite roentgenologic findings and some fatalities. The exact etiology has not yet been determined in either, and it is questionable whether they should be classified as pneumonoconioses until their status has been more accurately demonstrated.

When inhaled over long periods of time certain dusts may produce shadows in the roentgenogram which closely resemble those of silicosis, so that one should resist the temptation to make a diagnosis of occupational disease on the roentgenologic factor alone. Some physicians have had the embarrassing experience of making a "long distance" diagnosis solely from the roentgenogram, only to find out later that the person concerned had worked in an office all his life without ever having been subjected to dangerous dust. Even when the roentgenologic evidence is associated with a history of employment in a dusty industry, care should be exercised by the examiner to make sure that the occupation offers adequate exposure to dangerous-sized particles of material capable of causing actual damage to pulmonary tissue. It is still a common practice among physicians and roentgenologists who have insufficient knowledge of industrial environments or modern hygienic practices to arrive at premature and inaccurate conclusions simply because they have based their interpretations on too little information. Unfortunately they sometimes express very dogmatic opinions without stopping to consider the effect on the employer or the worker himself.

The distressing features of this conduct are that employees become needlessly alarmed, forsake their lifetime vocations, suffer financial loss and forfeit seniority. Industry is deprived of the services of skilled workmen, confronts lowered production and faces unjust and costly litigation—all because of unwarranted roentgenologic interpretation and unfamiliarity of the examiner with progressive industrial medicine and hygiene.

The number of unrelated conditions capable of producing roentgenographic shadows in the lungs simulating silicosis is constantly increasing. In 1946 I listed some 23 of these, which ranged all the way from certain cardiac afflictions to exaggerated linear markings representing pulmonary vascular changes due to advancing age.

Gardner[8] and others have demonstrated that silicosis is likely to develop only when significant concentrations of respirable-sized particles (those smaller than 10 microns, and especially those smaller than 3 microns) of free or uncombined silica have been inhaled over long periods of time (2 to 25 years, with an average of 10 years). This fact emphasizes the need for careful appraisal of injurious contamination by dust in the actual working places and correlation of this appraisal with the occupational history, clinical and roentgenologic findings when one is evaluating any case of suspected occupational fibrosis. The most important consideration in any such investigation is, "How is the man himself affected?" Although the amount of visible dust in the atmosphere around a specific job appears to be great, that fact does not necessarily mean that pathologic quantities of the particles are reaching the alveoli of the lungs. Accumulations at the breathing level and the defensive mechanism of the upper respiratory tract must be taken into account along with the length and constancy of exposure.

The absence of pathologic change in the presence of the inert dusts may be explained in part by several factors. The natural barrier to dust provided by the anatomic arrangement of the upper respiratory tract, the ciliated epithelium of the mucous membrane lining the bronchi down to the terminal bronchioles, and the phagocytic cells in the alveoli all serve to eliminate inhaled dust. When one considers a pulmonary ventilation rate of some 18 cubic feet per hour, which may increase from 50 to 80 cubic feet per hour on exertion, it is not difficult to see how well this defensive mechanism of the body works. The long period required for the development of recognizable silicosis, even under heavy exposure, attests the efficiency of the arrangement.

The size of the particles of the offending dust is also an important consideration. To be inhaled, dust must be air borne and also must be small enough to reach the alveoli. The diameter of an alveolus is approximately 250 microns, but, as pointed out previously, experience has demonstrated that very few particles of more than 10 microns in size ever reach them, certainly not enough to produce damage. And, as was also stated before, the inert dusts do not appear to have a chemical reaction on lung tissue, such as silica does. This factor is perhaps one of the most important reasons why these dusts do not cause fibrosis.

It may be said that up to the present time only free silica and asbestos have been believed capable of causing definite pulmonary fibrosis, and the reaction in each instance is quite different. Most of the other pneumonoconioses exhibit a characteristic tissue response. According to Gardner[9] the roentgenographic appearance in these cases consists of a mere accentuation of the normal, branching, treelike shadows, cast chiefly by the blood vessels. It represents a simple linear fibrosis and is difficult to distinguish from the mild accentuation of linear markings sometimes seen in roentgenograms of persons with no known history of exposure to dust. He designated this effect as "benign nonspecific pneumonoconiosis," and it includes every known reaction to mineral dust except that to soluble poisons, such as lead; the specific diseases silicosis and asbestosis, and certain "roentgenologic conditions," such as baritosis, stannosis and the pseudonodulation of arc welders. Numerous observers have pointed out that deposition of inert iron oxide into the lungs from occupations like welding, burning, polishing and grinding has resulted in pigmentation of the pulmonary tissue, which gives rise to discrete nodular shadows closely resembling those produced by free silica. Postmortem examinations of several patients with these signs have shown no evidence of the typical nodular fibrosis of silicosis.

Table 2.—*Classification of Pulmonary Conditions, Roentgenograms of Which Simulate Those of Silicosis*

- A. From Industrial Dusts
  - I. Organic
    - (a) Byssinosis
    - (b) Bagassosis
    - (c) Tabacosis
  - II. Inorganic
    - (Inert)
      - (a) Anthracosis
      - (b) Radiopaque Deposits
        - Barium (Baritosis)
        - Iron (Siderosis)
        - Tin
    - (Toxic)
      - (c) Reaction to Beryllium
    - (Proliferative)
      - (d) Asbestosis
- B. From Nonindustrial Dusts
  - I. Mycotic
    - (Yeasts and Molds)
      - (a) Aspergillosis
      - (b) Moniliasis
      - (c) Wood dust spore infection
      - (d) Coccidioidomycosis
      - (e) Blastomycosis
      - (f) Actinomycosis
  - II. Miscellaneous
    - (a) Miliary tuberculosis
    - (b) Sarcoidosis
    - (c) Mitral Stenosis
    - (d) Cancers (metastases)
    - (e) Vascular changes
    - (f) Miliary calcicosis ("wheatena")
    - (g) Erythremia
    - (h) Bronchiolitis

For the past two and a half years, because of roentgenologic findings suggestive of silicosis in the roentgenograms of the chest of some burners and grinders, my associates and I have been conducting experimental work at the Saranac Laboratory, in which studies animals have been exposed to representative concentrations of air-borne dust from grinding operations. Analysis of this dust shows relatively low amounts of free silica but very high quantities of iron oxide particles. Animals killed thus far demonstrate no pulmonary reaction except that comparable to reactions from other inert dusts. The work is continuing, and results will be published when sufficieint time has elapsed to produce valid conclusions. Other inert dusts, like those derived from tin and barium, are capable of causing changes in the roentgenologic pattern which, although very evident in the film, are nondisabling and do not result in fibrosis. They are very important, however, from the standpoint of diagnosis.

[8] Gardner, L. U.: Pathology of Silicosis, in Kuechle, B. E.: Second Symposium on Silicosis, Wausau, Wis., Employers Mutuals, 1935.

[9] Gardner, L. U.: The Pathology and Roentgenographic Manifestations of Pneumoconiosis, J. A. M. A. **114:** 535-545 (Feb. 17) 1940.

It has long been recognized that silica, or silicon dioxide (SiO_2), which makes up 60 per cent of the rocks and minerals of the earth's crust, is the specific cause of silicosis. It exists either in the free state or in combination with certain mineral oxides to form silicates, such as mica, clay and feldspar. Thus far only free silica is known to produce silicotic fibrosis of the lungs. The term free silica usually means quartz, of which there are many varieties. There are other forms of free silica, as shown in table 3.

TABLE 3.—*Forms of Free Silica, Causing Silicosis, Classic and Modified*

- Crystalline (Crystalline structure)
    - Crystobalite
    - Tridymite
    - * Quartz
- Cryptocrystalline (Crystal structure too fine to be easily distinguished)
    - Chalcedony
    - * Flint
    - * Chert
    - Jasper
    - * Tripoli
- Amorphous (Noncrystalline)
    - * Diatomite
    - * Silica Gel
    - * Vitreous Silica
    - Opal

* The compounds marked with an asterisk are those of the greatest industrial importance.

It has not been demonstrated authentically that silicates other than asbestos produce real pulmonary fibrosis. Pulmonary changes due to dusts containing them have been reported, but they probably resulted from small amounts of free silica, which existed as impurities. However, more investigation is necessary before one can make definite assertions about the innocuous character of these silicates.

Industrial pulmonary disease offers a real challenge to the general practitioner as well as the industrial physician. As the family doctor he may be called on to express his opinion as to whether changes observed in the roentgenogram of the chest are caused by occupation or not. Even though he is not directly associated with industry, most manufacturing concerns will welcome his interest and be more than willing to afford an opportunity for visits to the plant so that he can obtain first hand knowledge of actual working conditions. Through such contacts he will find that his appraisal of industrial diseases will be greatly enhanced, and the experience will prove to be fascinating and surprisingly valuable.

MANAGEMENT OF COMMON OCCUPATIONAL SKIN DISEASES

NELSON PAUL ANDERSON, M.D.
Los Angeles

The general practitioner in considering any patient with a cutaneous disorder of possible occupational nature has many problems to consider. In the first place there is the patient who generally comes to the physician as a private patient, i. e., not having been sent by either the employer or the insurance company. In such a case both the physician and the patient are primarily concerned with the problem of relief, i. e., that of treatment. This will be considered later. In addition to the relief of the patient, the physician should act (1) to prevent as far as possible aggravation or recurrence of the eruption, (2) to hold to a minimum the amount of time lost from work because of the cutaneous condition and (3) to prevent or minimize the occurrence of similar eruptions in other employees who may be similarly exposed.

In the second place there is the employer to be considered. He is not particularly interested in the medical problem except from its economic aspects. Nevertheless, the physician's relations with him should be harmonious because many times the employer will be called on to furnish information and technical data which may be absolutely essential to an intelligent handling of the patient's cutaneous condition.

Finally, there is the medicolegal aspect of the insurance carrier and industrial compensation. The insurance company must be furnished with a correct and etiologic diagnosis if this is at all possible. Such a diagnosis must be established on a scientific basis by a carefully taken history, by the dermatologic observations in any given case and occasionally, but not always, by patch tests. Reasonably accurate information should be furnished as to the temporary and permanent disability, the length of treatment, prognosis as to recurrences and the ability of the patient to resume his regular or ordinary duties.

The physician should be familiar with the compensation laws of the state in which he practices. In most states having such laws the patient is not compensated for the first week's absence from his work. Hence the physician who knows this will not be too quick to advise the worker to stay away from his job unless, of course, it is absolutely necessary. Another point, not generally understood, is that even if the patient's industrially caused eruption has been greatly aggravated by self-applied medication, nevertheless the condition remains compensable.

The importance of occupational dermatitis is revealed by the fact that it accounts for 65 per cent of all occupational disease exclusive of accidents in this country. Further, about 1 per cent of all workers will at some time suffer from an occupational dermatitis, and, finally, the average patient loses ten weeks from work.[1]

"An occupational dermatitis is a pathological condition of the skin for which occupational exposure can

---

This paper and the two preceding papers complete the symposium of seven papers on Industrial Medicine read at the annual meeting of the American Medical Association in Chicago, June 23, 1948. The papers by Dr. Leonard Greenburg, Dr. Elston L. Belknap, Dr. William C. Wilentz and Dr. John H. Foulger were published in THE JOURNAL last week.

Read in a Joint Meeting of the Section on General Practice and the Section on Preventive and Industrial Medicine and Public Health at the Ninety-Seventh Annual Session of the American Medical Association, Chicago, June 23, 1948.

1. Schwartz, L.: The Incidence of Occupational Dermatoses and Their Causes in the Basic Industries, J. A. M. A. **111:** 1523 (Oct. 22) 1938.

be shown to be the major causal or contributory factor."[2] The Committee on Industrial Dermatoses which formulated this definition also outlined in somewhat technical language the criteria for the diagnosis of occupational dermatitis.

Not only should these criteria be kept in mind, but they should also be in front of the physician when he takes the history. Such a history is the single most important aid in the correct diagnosis and management of any occupational dermatosis.

The following questions which adequately cover the same criteria from a slightly different angle have been formulated by Lane.[3]

1. Is the site of greatest exposure the site involved at the onset?
2. Is the site of the greatest skin involvement the site of maximum exposure?
3. Have other fellow workers suffered from similar eruptions?
4. Does the suspected causative agent produce eruptions of this type?
5. Is the occupation one in which similar cases have been observed?
6. Is the time relationship between exposure and onset of the eruption correct?
7. Is there any history of outside exposure to other irritants, e. g., as in gardening, hobbies, wearing apparel and cosmetics?
8. Are the cutaneous lesions present consistent with those known to have followed a similar exposure?
9. Is there a definite history of (*a*) the cutaneous eruption occurring after exposure to a suspected agent, (*b*) improvement and clearing of the eruption after cessation of work or transfer to another job where the suspected agent is no longer contacted and (*c*) relapsing of the cutaneous condition shortly after a return to the conditions of original exposure?
10. Are you sure of your diagnosis (patch tests)?

Essentially the same information is elicited in the special forms devised by Hall[4] and by Peck.[5] These can be used in place of the ordinary insurance blanks.

As emphasized by Lane,[3] it must be noted that these criteria do not apply in cases in which (1) considerable time has elapsed between the onset of the eruption and consultation with a physician, (2) the eruption has resulted from overtreatment with too strong medication, (3) the eruption has resulted from the improper or injudicious use of sensitizing medications and (4) there is an aggravation of a preexisting cutaneous disease by industrial contact or exposure.

INDUSTRIES IN WHICH OCCUPATIONAL DERMATITIS IS A PROBLEM

Schwartz[6] has listed the industries in which occupational dermatoses are most prevalent, with the incidence in each (percentage):

Synthetic resin manufacture	7.5
Chemicals and dye manufacture	7.0
Tanneries	3.5
Oil refining	3.3
Candy manufacture	3.0
Fabric dyeing	2.0
Rayon manufacture	2.0
Steel manufacture	1.5
Fur dyeing	1.0
Rubber manufacture	1.0
	1.0
	0.4

However, occupational dermatitis occurs in considerable numbers in persons in the food-handling trades, including housewives and domestic help. In fact, there is practically no industry, occupation, trade or profession in which occupational cutaneous disease is not at times a problem.

PHYSICAL EXAMINATION

The importance of conducting a physical examination of the entire body, including the scalp, feet and oral mucosa, should be noted. In case the eruption is caused by nonindustrial factors, this fact will often be detected by such an examination. In some cases an industrial cause of the eruption will be suspected but there will not appear to be sufficient contact with the offending agent to explain the various sites which are involved. In such cases close questioning of the worker will often explain the localization of the eruption to such sites.

PATCH TESTS

The patch test has been widely publicized almost to the point where, to paraphrase the common saying "he could not see the woods because of the trees," it has become impossible to see an industrial dermatosis because of patch tests. Nevertheless, the technic of the patch test, with its modifications and variations, the indications for patch tests and the value, limitations, dangers, interpretation and medical legal complications have been thoroughly and critically discussed by numerous dermatologists.[7] Patch tests are exceedingly valuable in certain cases, but they must not and need not be used in that great group of occupational dermatoses due to primary irritants. If patch tests are indicated, control studies should be done on the physician or his nurse. This point has not been stressed sufficiently.

Only about one third of the dermatoses occurring in industrial workers will prove to be of occupational origin. It will be comforting to the general practitioner to realize that in about 10 per cent of definite occupational dermatoses an exact etiologic diagnosis may be impossible.

INFECTIOUS ECZEMATOID DERMATITIS

One of the commonest cutaneous conditions occurring in association with occupational injuries is known as infectious eczematoid dermatitis. This condition may develop as a direct complication in a cut, scratch, abrasion, friction burn or other superficial injury of the skin. It is prone to develop in the region of wounds that have been neglected or improperly treated or in the neighborhood of pyogenic infections, such as a furuncle, otitis media or a draining sinus such as may develop following a compound fracture or osteomyelitis. Many times the history of an injury will not be obtained unless the patient is specifically questioned regarding such an injury.

In one group of cases it is the direct result of bacterial sensitization of the skin in the neighborhood of a wound. In the other group of cases it follows the chemical sensitization of the skin by such agents as the mercurials, iodine or sulfonamide drugs. Granulating wounds, such as burns with secondary infection, are especially apt to become sensitized. As pointed out by Sneddon,[8] in such cases the epithelial cells are subjected to closer contact from such external agents than occurs with intact skin. He further noted that the site of the wound was also very important. In localities with deficient blood supply there is less resistance or poorer nutrition of the cells and the healing time is prolonged. Both of these factors favor the development of sensitization and especially so when in addition a chemical agent is applied which possesses decided sensitizing powers. Once the process has started it seems to possess the power of self perpetuation and is definitely autoinoculable, e. g., in scratch marks or at sites of microscopic trauma such as occurs from adhesive tape.

The resulting cutaneous picture shows one or more sharply outlined patches, which are often coin sized or larger. These patches are composed of superficial papulovesicules or pustules. These easily rupture and produce a moist raw oozing edematous patch which, because of its annular appearance, is often mistakenly diagnosed as a ringworm or fungous infection. New vesicles and pustules develop peripherally or at a distance, and these patches may combine to form larger areas of dermatitis with a profuse thin serous or seropurulent discharge. Single or grouped crusted or oozing vesicles frequently develop in the neighborhood. Later the lesions may become dry and scaly, but most frequently they remain covered with a dry granular varnish-like exudate which cracks or splits, allowing the exudation of serum. There occur repeated exacerbations and remissions, although subjective symptoms are relatively absent or mild. The condition is exceedingly resistant to therapy.

Cultural studies are negative for fungi, but staphlyococci and/or streptococci are usually isolated on ordinary culture mediums. It should be noted that the dermatitis which is seen following exposure to the chromates in the airplane industry may simulate infectious eczematoid dermatitis both in its morphologic aspects and patchy distribution. This was first pointed out by Hall.[9]

TREATMENT

What Not to Use.—In dealing with an industrial dermatosis, it is probably more important to know what not to use than to know any one particular remedy. Many minor industrial or occupational dermatoses are converted into major ones by either sensitizing or irritating local applications or remedies. Thus one sees irritation and sensitization from such applications as the mercurials. These include ammoniated mercury, tincture of merthiolate, tincture of metaphen and certain proprietary disinfectants or sterilizing solutions. As a matter of fact, most of these so-called mercurial antiseptics, at least when in aqueous solution, are valueless for their supposed antibacterial action, as has been shown recently.[10] One must not forget that tannic acid ointment contains 1 : 5,000 merthiolate as a preservative.

Experiences with the local use of the sulfonamide drugs in the past decade certainly have demonstrated the fact that these drugs, particularly sulfathiazole, are potent sensitizers.[11] They have no place in the routine treatment of cuts, abrasions, infected wounds or burns or pyogenic infections of the skin.[12]

The experiences of most dermatologists with the local use of penicillin have revealed that this antibiotic is a potent sensitizer. It may either cause a severe sensitization dermatitis or aggravate an existing condition without producing a definite dermatitis.[13] What, however, is more important with regard to both penicillin and the sulfonamide drugs is the fact that such locally produced sensitivity frequently leads to a generalized sensitivity. This may be of such a high degree as later to prevent the internal use of these valuable therapeutic agents.

The use of butesin picrate ointment for the relief of burns should be mentioned. There are two potent sensitizing agents combined, the local anesthetic butyn and the picric acid radical. All local anesthetics, including dibucaine hydrochloride (nupercaine hydrochloride®), ethyl aminobenzoate, tetracaine hydrochloride (pontocaine hydrochloride®) and metycaine hydrochloride® · (racemic-3-benzoxy-1-[2-methylpiperidino]-propane hydrochloride), are decided sensitizers, and their use, particularly on wounds and open granulating surfaces, is fraught with far greater danger to the patient than any temporary benefit derived from their local anesthetic effect, which at the best is very fleeting.

Acriflavine and proflavine of the acridine dye group are also so-called first aid drugs, the use of which could be easily dispensed with. Actually acriflavine may touch off a dermititis due to sulfonamide drugs.[14] A combination of proflavine and sulfonamide mixtures is more damaging to tissues than either substance alone.[8]

In addition to these sensitizing agents, it is a good general rule to avoid the use of ointments containing phenol, resorcinol and nitrofurazone. In general, dermatologists agree with Lyons [15] when he says that local chemotherapy of wounds is unnecessary and undesirable.

In this connection I am sure that sensitivity to adhesive tape is commoner than the literature would indicate. Adhesive tape should be used sparingly, if at all, on the skin of persons suffering from (1) polyvalent sensitivities and (2) infectious eczematoid dermatitis or so-called nummular eczema. In the former it is apt to provoke a nonspecific flare, and in the latter condition new patches of nummular eczema are prone to occur in nearby areas of skin which have been irritated by adhesive.

Dyes and Paints: The custom of using various pigments and paints is probably a "hold over" from the ancient days of the "medicine man" and the "witch doctor." The more vivid, violent and striking the hue and color, the more the patient is impressed. The "medicine man," however, had the advantage that most of his pigments were of vegetable origin. In modern times the fashion has been to use iodine, merbromin, merthiolate,® nitromersol, methylrosaniline chloride, bismuth violet® (contains 4 per cent bismuth ammonium citrate and 96 per cent crystal violet), carbolfuchsin, picric acid, brilliant green and similar preparations of variegated colors. In general most of these are organic dyes which, if they do not cause a secondary contact dermatitis, at least succeed in masking the clinical picture. In general if one feels that the patient must have that "new look," then less trouble and more benefit will be obtained by the use of aqueous methylrosaniline chloride in a 1 or 2 per cent solution. Rarely has the use of methylrosaniline chloride been followed by the development of permanent discoloration of the skin, which is of the nature of a "traumatic tattoo."[16]

ULTRAVIOLET RAYS

Many physicians employ ultraviolet rays in the management of dermatoses of an undeniable occupational nature. Without commenting on its value, I should like to state that, if one must use ultraviolet rays, many complications and untoward effects may be avoided by always employing suberythema doses.

COOPERATION WITH PLANT ENGINEER AND PERSONNEL DEPARTMENTS

The plant or safety engineer can frequently be of great help in the placing of adequate exhaust systems in situations where noxious dusts or fumes are a factor, as in electroplating, or in the modification of certain industrial processes, such as the addition of gelatin to sulfate baths when the latter are used as a substitute for cyanide baths.[17] In some chromium plating operatons it is estimated that from five to ten times the amount of chromium converted into chromium plate was lost in the spray or mist over and about the plating tank. The use of a floating or surface application of plastic chips has reduced the concentration of chromic acid in the air by one hundred fold.[18] In small plants without a safety engineer, such a service can be secured from the insurance carrier.

There is no doubt that in industries with a high incidence of occupational dermatitis, a carefully taken preemployment history and examination would do a great deal from a preventive point of view.

PROPHYLACTIC

The use of impervious gloves, gauntlets, masks and other protective garments has been adequately stressed by Schwartz. In any special problem of protection the tremendous wealth of experience and knowledge of the Dermatoses Investigation of the United States Public Health Service, under the supervision of Dr. Paul C. Campbell Jr., is open to all simply for the asking. Dermatologists frequently take advantage of the special knowledge which this agency possesses. There is no reason why the general practitioner should be hesitant in asking for aid in any special problem.

The use of mild soaps, detergents and cleansing agents will do much to eliminate a prolific source of cutaneous irritation. On the other hand, the use of harsh gritty soaps and cleansing agents or turpentine, paint thinners and degreasing solutions should be condemned.

In instances where industrial dermatitis reaches epidemic proportions the plant should be visited personally by the physician along with the safety engineer. Usually in such instances there are two chief factors. First, the workers are in excessive contact with definite irritating or sensitizing materials. Secondly, the washroom facilities are generally inadequate, with no hot water, soap or towels. If the doctor fails to secure adequate washing facilities, either the insurance carrier or the labor union may secure appropriate action.

Protective creams, lotions, films or greases undoubtedly have some value. There are a great many of them on the market, and certain of them may be of value in certain occupations. In general, however, ordinary wool fat is about the best as an all-purpose protection cream. In fact, as so aptly stated by Schwartz, " . . . the chief value of a protective cream is that it practically forces the worker to wash it off."

ACTIVE TREATMENT

It is practical in cases of acute and more or less generalized dermatitis, in which there is often involvement of the face and neck, ears, eyelids, genitalia, hands, forearms and feet, for the physician to warn the patient that his eruption is "going to get worse before it gets better." All doctors have seen examples of this in the early stages of poison ivy or poison oak dermatitis. In so warning the patient one convinces him that one knows what the course of his eruption will be and so retains his confidence.

All experienced dermatologists will agree that most cases of industrial or occupational dermatitis are overtreated, sometimes by the physicians, but more often by the patient in the use of proprietary remedies advocated by some well meaning friend or druggist. The solution is obvious. In acute dermatoses, regardless of the cause, the physician will do well to confine his local topical remedies to those which are soothing or at least innocuous. To paraphrase a statement by Crawford, occupational cutaneous diseases, like people, respond best if treated gently.[19] These remedies are in general solutions rather than salves or ointments, and as representative examples the following solutions suitable for wet dressings may be mentioned. In fact, on a violently red moist weeping oozing skin, nothing else should be applied.

(*a*) Aluminum acetate solution (Burrow's solution) diluted with 12 to 16 parts of water
(*b*) Plain milk (cold) 4 parts, lime water 1 part
(*c*) Boric acid, 2 to 4 per cent (warning: take care, do not use over extensive areas either in solution or ointment form)
(*d*) Magnesium sulfate (saturated)
(*e*) Sodium chloride solution, 0.9 per cent
(*f*) Starch solutions (boiled)
(*g*) Weak sodium bicarbonate (baking soda) solutions

In general wet dressings should not be used on over one third of the body surface. They should be changed frequently, i. e., every two to three hours, so that the strength of the solution is not increased by evaporation. The use of an impermeable covering, such as wax paper or oiled silk, is optional.

In subacute and chronic stages, when there is dryness, scaling, thickening and fissuring, various ointments and oily preparations are indicated.

These include such preparations as "1-2-3" ointment modified as follows:

Liq. aluminum acetate	5.0
Distilled water	5.0
Wool fat	20.0
Lassars' paste *	30.0

* Lassars' paste is composed of starch 7.5, zinc oxide 7.5 and white petrolatum 15.0.

For extensive areas and in warm weather oily shake lotions are to be preferred.

Ormsby's bismuth cream lotion:	
Bismuth subnitrate	4.0
Zinc oxide	8.0
Olive oil and lime water—equal parts to make	240.0
Apply locally several times daily.	
Rosen's emulsion burrowi:	
Wool fat anhydrous	30.0
Olive oil (pure)	120.0
Heat in mortar and mix well	
Add zinc oxide	30.0
Talc	30.0
and mix well	
Add aluminum acetate solution (1, 2 or 3%)	3.0 to 9.0
and mix well	
Add lime water (fresh) to make	300.0
Apply locally several times daily.

TREATMENT OF SECONDARY PYODERMAS

In instances where secondary infection is present, the following preparation (alibour water) may be used as continuous wet compresses. This is very useful, effective and practically without any danger of causing a sensitization dermatitis.

Copper sulfate	1.6
Zinc sulfate	5.6
Saturated camphor water to make	240.0

Dilute 2 tablespoonfuls to a glass of tap water and apply as a continuous moist dressing.

This preparation may be used anywhere on the body, including the eyelids and genitalia. The mild green discoloration which is deposited on the skin is a valuable index or guide as to whether the patient is actually using the solution.

Another useful wet dressing in treating secondary pyogenic infections is 0.25 to 0.5 per cent aqueous solution of silver nitrate. The black stains which result are somewhat disfiguring, although only temporary, but do make one hesitate to use this preparation on exposed surfaces.

The staining qualities of potassium permanganate in 1 : 5,000 or 1 : 10,000 aqueous solution are such that many dermatologists do not use this otherwise valuable remedy.

Tyrothricin [20] is one antibiotic the local use of which has not resulted in sensitization dermatitis. It is applied either in the form of wet compresses in a strength of 0.25 to 0.5 per cent or in a vehicle favoring penetration, as in intraderm® tyrothricin solution (solution containing 0.1 per cent tyrothricin [gramicidin fraction not less than 20 per cent] in a vehicle of water 89 per cent, propylene glycol 10 per cent and an alkyl aryl sodium sulfate 1 per cent).[21]

Bacitracin, also a newer antibiotic, has been used locally in the treatment of the pyodermas with encouraging results, and so far there have been very few reports of sensitization following its use.[22]

SUMMARY

Some general aspects of occupational skin diseases are considered. An outline of simple and effective treatment for occupational dermatoses and some of its complications is presented.

2007 Wilshire Boulevard.

PANEL DISCUSSION

ON PAPERS BY DRS. LEONARD GREENBURG, ELSTON L. BELKNAP, WILLIAM C. WILENTZ, JOHN H. FOULGER, REX H. WILSON, L. E. HAMLIN AND NELSON P. ANDERSON

Dr. L. T. Fairhall, Milwaukee: For several years the diagnosis of lead poisoning has been encumbered with an aura of mysticism which, while it must have discouraged some, has encouraged others to surround it with even greater difficulties. There is no single quantitative factor leading to the immediate diagnosis of lead poisoning. It is true that various criteria have been proposed which have been thought to be sufficient to make a clearcut diagnosis. However, as these criteria have been examined, they have been found to be incomplete, and, instead, the true diagnosis of lead poisoning has involved the summation and integration of a number of factors. For instance, the value of porphyrin excretion or blood porphyrin has been broached by investigators at various times as an indisputable index of lead poisoning but has been found by other investigators to be variable or without significance in true lead poisoning. With reference to the urinary excretion of lead, an increased output has, as Dr. Belknap has stated, significance only of lead absorption; of itself, it indicates only passage through or removal from the body without in any way implicating damage to the human organism; however, it is significant and helpful as an indication of pronounced absorption of lead. It is fortunate in this regard that the quantity of lead in the urine, which is of significance to the diagnostician, lies within values which lend themselves to convenient determination in the laboratory. In other words, the order of magnitude of urinary lead lies within the range of relatively significant fractions of a milligram per liter and not within the range of micrograms per liter. One factor on which Dr. Belknap places weight is basophilic stippling. While this has been accepted as one of the definite criteria of lead poisoning, it has been a sort of diagnostic football and has been kicked about more than it deserves. In spite of the fact that a few stipple cells occasionally appear in the blood stream of normal persons, and the further fact that stippling has been shown to occur in certain diseases and intoxications, Belknap, in his long study of lead poisoning and persons exposed to lead, has succeeded in placing this criterion of lead poisoning on a firm basis. The test or yardstick by which the efficacy of this means of diagnosis may be measured is indicated by the experience which he cited, namely, that the incidence of disabling lead poisoning promptly fell from 20 per cent to 0 per cent in a single lead storage battery plant and that by such medical control he has been able to keep these employees free from disabling lead poisoning for eleven years.

Dr. R. T. Johnstone, Los Angeles: Dr. Belknap, how many red blood cells on the average are represented by 50 fields, as blood smears are studied by you?

Dr. E. L. Belknap, Milwaukee: About 10,000 red blood cells per 50 fields. The number of red cells per oil immersion field is about 200; thus, in 50 such fields, about 10,000 cells are counted. To gain the corresponding number of stippled cells per million red cells one would simply multiply the factor by 100. Of course, one should realize that is a rather rough index, because the number of red cells vary even in the normal person.

Dr. Johnstone: Dr. Wilentz, what do you recommend regarding the use of blood transfusion of whole blood in acute lead poisoning?

Dr. W. C. Wilentz, Perth Amboy, N. J.: I do not object to using it if I think the patient is that sick.

Dr. Johnstone: I do not believe that there are many cases of intoxication so severe that one need use it in advance.

Dr. Wilentz: I have never found it necessary.

Dr. John H. Foulger, Wilmington, Del.: Nor I.

Dr. Johnstone: Dr. Foulger, do the solvents you discussed produce menstrual disorders?

Dr. Foulger: I know of no evidence that the solvents discussed produce menstrual disorders. In fact, I am inclined to think that very few chemicals, if any, as used in industry, interfere with menstruation. During the war, my co-workers and I studied numbers of women exposed to very active chemicals and found no such effects.

Dr. Johnstone: Dr. Wilson, what is the usual time in acute carbon tetrachloride poisoning before nephrosis or hepatitis develops?

Dr. R. H. Wilson, Akron, Ohio: The process of nephrosis or hepatitis probably starts very soon after the beginning of exposure. Manifestations of nephrosis or hepatitis probably occur in six to twenty-four hours in acute poisoning.

Dr. Johnstone: Would you say, Dr. Wilson, that where there are signs of some intoxication present, actual observations

acute nephrosis or uremia will be evident in a week or ten days?

DR. WILSON: That is correct.

DR. JOHNSTONE: Dr. Wilson, one speaker included parkinsonian symptoms among the conditions due to industrial poisoning by carbon disulfide. Is the evidence clear on this point?

DR. WILSON: No.

DR. JOHNSTONE: Dr. Greenburg, do the industrial doctors have evidence that absorption of mercury could cause parkinsonian disease, for example, in a man who works for years treating grain for a seed company?

DR. LEONARD GREENBURG, New York: I have seen men in whom tremor has developed. Undoubtedly this will be true in certain cases. That is evident if one examines the handwriting. Psychic disorders also develop, but there is no reason to confuse that with straight parkinsonian syndrome, not related to occupation.

DR. JOHNSTONE: Is there any substantial evidence, Dr. Wilson, that delayed leukemia may result years after benzol intoxication?

DR. WILSON: Not in my experience. The acute benzol intoxication is usually manifested, as far as blood changes are concerned, immediately. I have never seen a case of late acute leukemia. It may develop in chronic conditions.

DR. JOHNSTONE: Dr. Wilentz, is hospitalization necessary in the treatment of lead intoxication?

DR. WILENTZ: I do not know a better place to receive treatment or a place where one can get better so quickly. Some men do not like it. I am sure that intensive therapy at the hospital will shorten disability. It is important that intravenous calcium therapy be given around the clock, and I know of no other place where this can be accomplished except in a hospital.

DR. JOHNSTONE: There is one question turned in which I cannot quite understand: What are the autopsy observations (I suppose) of encephalitis following lead poisoning?

DR. BELKNAP: Deaths due to lead poisoning are extremely rare in adults. There have been very few cases of encephalopathy due to lead in modern industry since the lead hazard in the ethyl gas industry was controlled entirely on the basis of engineering protective devices. However, men did die in that industry and studies have been made and reported. That is primarily a pathologic problem.

DR. JOHNSTONE: Dr. Sander, how can one accurately determine the nature of a dust, such as the difference between iron dust and silica? I suppose that the questioner had in mind determining the nature of the dust in the plant and then analyzing the collected dust by roentgen diffraction.

DR. SANDER: Chemical analysis, petrography and animal experimentation, in addition to the roentgen diffraction analysis, are the methods used to differentiate free silica from other dusts. Animal experimentation is especially useful when the silica content of a dust is known to be low. As Dr. Hamlin has said, he has had experimentation under way at the Saranac Laboratory for three years to determine whether the dust from grinding cleaned steel castings contains enough free silica to cause silicotic nodulation. The animals studied so far show no evidence of silicosis, but do show inert iron deposits in the lungs without any fibrotic reaction.

DR. JOHNSTONE: Dr. Hamlin, what is the incidence of pneumonia in the dusty trades?

DR. L. E. HAMLIN, Chicago: The incidence of pneumonia in my experience has been very low. In the old days pneumonia was a problem in the foundry industry, but with improved working conditions and better hygienic surroundings, there is very little today. In the mining industry in Upper Michigan, where I practiced for ten years, silicosis was common. Nodulation was extensive; yet, the incidence of pneumonia was extremely low. In fact, some of us felt that fibrosis was a factor as far as limiting the spread of pneumonia was concerned.

DR. JOHNSTONE: Dr. Sander, what is "welder's lung?"

DR. OSCAR A. SANDER, Milwaukee: When welders are exposed to excessive concentrations of fumes in confined and unventilated areas, roentgen changes of the lungs may develop after more than five years which somewhat resemble the change in silicosis. The stippled or pseudonodular pattern is due to inert deposits of iron oxide particles in the lymphatic vessels surrounding blood vessels. An important differential point between this benign pneumoconiosis and silicosis is that the root lymph nodes are not enlarged in the former as they are in the latter.

DR. JOHNSTONE: This question is directed to Dr. Belknap, by Dr. J. S. Alley of Midvale, Utah: How soon will stippling occur after massive exposure to concentrated lead fumes? Will other acute symptoms develop first?

DR. BELKNAP: Where lead exposure is massive enough to produce symptoms in a few hours, as with tetraethyl gas exposure, stippled cells do not appear as rapidly as symptoms. I have not had that type of exposure closely under my observation, but I would assume that it would take at least two or three days for stippled cells to develop. I did see this in a maintenance man exposed to lead fumes caused by using a welding torch on an oven where there had been much contaminating lead oxide. He showed a lead line of the gums and stippled cells within a week. However, he did not have enough massive exposure to have any disability. I have also seen men cutting lead-painted steel and those who metallized metal with lead-wire and blow torches, show many stippled cells coincident with symptoms arising within ten days after beginning lead exposure.

DR. JOHNSTONE: Dr. Hamlin, what type of treatment exists for the patient with chronic pulmonary fibrosis?

DR. HAMLIN: There is no definitely established treatment. Once pulmonary fibrosis has developed it is permanent. A worker with this condition should be removed from further harmful exposure. Aluminum therapy has been advocated and is now being used in a number of industries here and abroad. I have had no personal experience with it, but the status of it at this time seems to be that, while it does appear to prevent further progression of fibrosis, its value as a specific form of treatment has not been proved conclusively.

DR. JOHNSTONE: Are benzene fumes a causative factor in pulmonary neoplasms?

DR. WILSON: Not that I know of.

DR. JOHNSTONE: I do not believe that there is any evidence of that effect as yet.

Copper as a Snail Killer.—Copper has long occupied a unique position as a molluscicide. Its toxic action against freshwater snails and green algae, together with its comparative harmlessness to higher vertebrates and phanerogamic vegetation, have, when considered in conjunction with its relative inexpensiveness, made it the most favoured agent for snail-control campaigns.

A voluminous literature has appeared on the efficacy of various copper preparations — of which copper sulphate is the most popular—when tested against snails both in vitro and in the field, and large-scale snail-destruction campaigns, sometimes combining the use of copper with periodic drying, have been carried out in Egypt, Southern Rhodesia and elsewhere, as part of bilharzia-control schemes.

Khalil (1932) has given a detailed account, based on an extensive series of experiments in Egypt, of the value and limitations of copper as a snail-killer, and the developments in its use, which have been going on since Leiper's classical researches, are described in numerous publications by Barlow and Abdel Azim and others, who have established the real value of 5 parts per million of copper sulphate as a means of control in the field.—S. G. Cowper, Effect of Certain Inorganic and Vegetable Substances on the English Pond Snail Planorbis Corneus (Linné, 1758), *Annals of Tropical Medicine and Parasitology*, September 1948.

TREATMENT OF ALCOHOLISM WITH TETRAETHYLTHIURAM DISULFIDE (Antabus®)

ERIK JACOBSEN, M.D.
and
O. MARTENSEN-LARSEN, M.D.
Copenhagen, Denmark

During some experiments performed with tetraethylthiuram disulfide (antabus®) in the laboratory, Dr. Jens Hald and one of us (E. J.) discovered that persons who have ingested this substance showed symptoms after consumption of alcohol which differed quantitatively and qualitatively from the common picture of alcoholic intoxication. The discomfort after alcohol consumption in persons treated with tetraethylthiuram disulfide was so intense that we decided to submit this drug to trial as a remedy for alcoholism. The clinical experiments were conducted by one of us (O. M.-L.). The present report includes a short review of the results obtained in the investigations on the biochemical mechanism of this effect and of the clinical results on 100 persons with alcoholism who were treated for six to twelve months.

PHARMACOLOGIC CONSIDERATIONS

Tetraethylthiuram disulfide is a white, or slightly yellow, powder which is insoluble in water. It is relatively nontoxic. The fatal dose is 2 to 3 Gm. per kilogram of body weight for puppies and rabbits.[1] The fatal symptoms are a gradual depression with ataxia and decreased respiration and pulse.[1a] Biopsy shows congestion of the lungs, advanced degenerative changes in the kidney and somewhat less intensive changes in the liver. The cellulosity of the bone marrow is greatly reduced.[1b]

Rats were given 1 mg. daily and rabbits 60 mg. daily for ten months without any influence on growth, body weight, appearance or blood picture.[2]

In man, no effect was observed after single doses of 3 Gm., or after doses of 0.25 to 1 Gm. taken daily for months. After such doses, no subjective or objective effects were noticed in most persons. Exceptions are mentioned later under after-effects. Elimination from the body is slow. In man the effect of 1.5 Gm. can be traced seven to eight days after ingestion, and the effect after a single dose in rabbits persists for seventy-six to ninety hours. No antabus® is excreted in the urine.

When a human subject has taken antabus® (e. g., 1 Gm.) twelve hours previously, the intake of alcohol results in the following symptoms: After five to fifteen minutes the person has a feeling of heat in the face. A few minutes later an intense vasodilatation is observed in the face and neck, making the whole area purple-red. Some patients even show vasodilatation on the upper part of the chest and the arms. Characteristic is the vasodilatation in the scleras. Slight edema in the loose connective tissue under the lower eyelids is also typical. The vasodilatation in the face is accompanied with a decided increase in skin temperature in this area.[3] The pulse rate is increased to 120 to 140. The blood pressure is unaltered or slightly depressed. The cardiac output is increased about 50 per cent in resting persons and only slightly (5 to 15 per cent) in persons doing moderate muscular work. The ventilation is increased, with a corresponding decrease in alveolar carbon dioxide.[4] The effect on the respiration and the pulse rate is eliminated during inhalation of pure oxygen. This suggests that the symptoms are due to a stimulation of the chemoreceptors in the carotid sinus. The volume of the respiratory dead space is increased or unaltered.

Sometimes nausea begins thirty to sixty minutes after consumption of alcohol. In such cases the intense flushing disappears and is replaced by facial pallor and a considerable fall in systolic and diastolic blood pressure. Copious vomiting may occur. Occasionally, the vomiting may begin suddenly with no, or a very short, nausea stage. Higher doses of alcohol, in some patients, result in dizziness, and a few times a patient has been unconscious for as much as a half-hour.

No other objective symptoms are observed. These symptoms are generally accompanied with an intense feeling of discomfort to the patient, who has a pulsating headache, palpitations and subjective dyspnea. In most cases, the patient notes a constrictive feeling in the neck, as though "the collar has become too tight." To this can be added a feeling of a "premature hang-over," which is difficult to describe, but which is highly disagreeable. In summary, the discomfort is so intense that, once experienced, it prevents an overwhelming majority of patients from further attempts to take alcohol as long as they are influenced by antabus.®

After moderate doses of the drug, the combustion rate of alcohol in man is the same whether or not the person has taken antabus.®[2] The same is seen in rabbits after moderate doses,[5] but, after ingestion of large doses of antabus,® the combustion rate can be considerably decreased. It is still unknown whether heavy doses, even in man, result in a similar decrease in the rate of elimination.

More important is the fact that the blood acetaldehyde level is increased after treatment with antabus® and subsequent consumption of alcohol to a concentration five to ten times higher than that seen when the same doses of alcohol are given to untreated persons.[6] Acetaldehyde is also excreted through the lungs and gives the expired air the intense, characteristic smell of the substance. When acetaldehyde is infused intravenously at such a rate that the concentration in the blood is kept on a level corresponding to that seen after the administration of antabus® plus alcohol, the same symptoms are seen in the same intensity.[7] Even here, the effect on ventilation and alveolar carbon dioxide is abolished after inhalation of pure oxygen. There can be little doubt that the clinical effect of alcohol after ingestion of antabus® is due to an increased

---

Dr. Jacobsen contributed the theoretic portions and Dr. Martensen-Larsen the clinical portions of the paper.

From the Biological Laboratories, Medicinalco Ltd., and Flakvad Sanatorium for Alcoholics, Rungsted Kyst, Denmark.

In the United States the rights for the distribution of antabus® have been assigned to Ayerst, McKenna & Harrison Limited, under whose auspices clinical investigation of the drug is now being conducted in this country.

concentration of acetaldehyde, which is formed by some unknown reaction of antabus® on the enzymes oxidizing alcohol in the organism.

The symptoms are seen after the ingestion of any alcoholic beverages and also after the taking of pure ethyl alcohol diluted with distilled water. The increase in skin temperature is seen when the blood alcohol is increased as little as 5 to 10 mg. per hundred cubic centimeters. The symptoms are fully developed at a concentration of 50 to 100 mg.; unconsciousness results at 125 to 150 mg. Some persons, especially heavy drinkers, at the first test seem to tolerate a rather high percentage of alcohol in the blood. By continued use of antabus,® the tolerance in most persons is considerably decreased. The effect persists as long as the alcohol remains in the blood (generally one to one and one-half hours for each average-sized drink taken). When the symptoms begin to fade, most patients feel exhausted and sleepy. After a few hours' sleep, they are completely recovered.

The hypersensitivity to alcohol generally begins three to four hours after the ingestion of a single dose of antabus® and is fully developed during the next twenty-four hours. Experiments with rabbits show that acetaldehyde formation increases with increasing concentrations of alcohol in the blood and with increasing doses of antabus,® up to a certain dose. The saturation dose of the drug in rabbits is 0.3 Gm. per kilogram of body weight. It is still uncertain whether a similar saturation dose is obtained in man. These observations are valid even for human beings, since increasing doses of both antabus® and alcohol increase the clinical effect.

CLINICAL EFFECT

All persons with alcoholism who have consulted us since December 1947 were treated with antabus.® Up to December 1948 the total number of patients was 550. The results for a small number have already been described.[8]

The first patients were treated on consultation. Later, it was found advisable to take those with the severer conditions, or those for whom alcoholism had caused an acute crisis in the home or family, into the sanatorium. The visit there has been short (from one to three weeks), since it is best to continue treatment in the patient's usual environment as soon as possible. Patients taken into clinics are treated in open wards and are allowed to pay short visits to their offices and homes. It is important for rapid mental and social restoration to bring patients back into their ordinary lives as soon as possible, so that they may learn to live nonalcoholic lives among normal drinkers.

The dosage varied during the period of experimentation. At the beginning, treatment was begun cautiously, with small doses which were increased with time since no severe after-effects occurred. In the material presented here, the treatment has been as follows: On the first day, 1 to 2 Gm. of antabus® was given; on the next two days, 0.75 to 1 Gm. Thereafter, 0.06 to 0.75 Gm. was administered daily. As will be stated later, some of these doses were too small. For this reason, we increased the initial dose to 2 Gm. the first day and 0.75 to 1 Gm. the following two days. The dose depends on the individual person and is adjusted so that flushing occurs after 5 Gm. of alcohol (one third to one half of a drink) is ingested. This dose lies generally between 0.25 and 0.75 Gm. daily. In most cases, the patients were given a "test drink" on the third day of treatment to experience the effect of alcohol. The patient was asked to drink as he was accustomed to, with the usual interval between the drinks, until he was forced to stop. As a rule, this point was reached after two and one-half to four and one-half drinks. The last half drink generally remained untouched. The test drinking was usually under observation. However, some patients feel tempted to drink in a bar, with instructive results.

The patients were followed with regular examination of the blood (red and white blood cell counts and hemoglobin determinations), tests on urinary albumin, bile pigments (and urobilin) and hepatic function (thymol turbidity test) and electrocardiograms. No pathologic changes have been observed. About 20 per cent of the patients (18 of the first 100) complained of tiredness, which persisted one or two months but disappeared during continued treatment. It was necessary to stop medication for this reason in only 1 patient. A few patients noted decreased sexual potency, but this complaint was also transient. Generally, the drug exerted a calming influence on the patient which was not at all undesirable. In 15 per cent of the patients (12 of the first 100) sleep was considerably improved, so that the use of sedatives was unnecessary.

No other after-effects were seen in the material here studied, or in the 550 patients under our control. Since September or October 1948 antabus® has been widely used in Denmark, Sweden, Iceland and Finland (on several thousand patients). A few other untoward after-effects have been noted and reported to us. One or two patients have shown a slight allergic cutaneous reaction, which disappeared readily after medication was discontinued. In 2 or 3 patients, a manic state developed during the first weeks of treatment. In these instances, it seemed as though the manic state was preceded by a feeling of dizziness and restlessness. The doses in these patients were comparatively high. They were hospitalized and, after discontinuation of the medication, the psychiatric symptoms faded within a few days.

The reaction after alcohol consumption may in some persons be either too severe or too slight. Severe reactions are generally seen after large doses of alcohol and can be rather alarming to the patient and his relatives. The following case was described by Linden.[9]

> After doses of antabus® of 1.5 to 1 Gm. and a moderate amount of alcohol, a 56 year old man fainted and had convulsions. He was cyanotic and appeared to be dying. The electrocardiogram showed an auricular flutter with 2:1 auriculoventricular block. He was given strophanthin as a stimulant and treated with oxygen. He began to recover after a half hour and was completely recovered in two hours. The heart function was normal the next morning.

Convulsions are seen in a few patients and are probably due to intense hyperventilation. The treatment for these patients is inhalation of carbogen® (95 per cent oxygen and 5 per cent carbon dioxide) and stimulation of the heart. In case of restlessness, moderate doses of quick-acting barbiturates may be of value.

Too slight reactions are also seen. A few patients flush and have palpitations or perhaps vomit after a few drinks. If they continue to drink beyond this point, their uneasiness suddenly disappears and they can continue drinking without any ill effects. This happens especially when the dosage is too small. It was seen after doses of 0.25 Gm. daily and in 1 patient after 0.5 Gm. daily in connection with diarrhea.

[8] Martensen-Larsen, O.: New Lines in Treatment of Alcoholics, Ugesk. f. læger, **110**:1207 (Oct.) 1948; Treatment of Alcoholism with a Sensitizing Drug, Lancet **2**: 1004 (Dec. 25) 1948.

[9] Linden, L.: Complications with Antabuse, Svenska läk-tidning. **45**: 1469 (Dec.) 1948.

When the medication is started during a period of heavy drinking, the uneasiness may be noted by the patient to a minor degree, and he will not discontinue drinking until after a few days' treatment. Three patients in the present material continued drinking at the beginning of treatment for one to two weeks in decreasing doses in spite of medication. One of these patients was socially recovered after nine months of observation and had no relapses. The other 2 were regarded as much better after an observation period of six months.

Table 1.—*Results in Persons with Alcoholism After Six Months of Treatment with Antabus®*

	Socially Re- covered	Much Better	Some- what Better	Un- changed	Total
Habitual drinkers	21	6	4	7	38
Weekly drinkers	7	4	5	4	20
Periodic drinkers	24	9	3	5	41
	—	—	—	—	—
Total	52	19	12	16	99
Medication					
Takes tablets daily by himself	14	2	1	0	
Takes tablets daily, but must be reminded	6	5	0	1	
Takes tablets daily, but must be reminded energetically	1	1	0	0	
Takes tablets occasionally	11	9	8	1	
Takes no medication	20	2	3	14	
Attitude of relatives					
Good understanding and active cooperation	33	10	1	2	
Home conditions favorable, but relatives neutral or ignorant of treatment	7	5	1	2	
Relatives unintelligent or unable to comprehend the idea of the treatment	3	2	4	3	
Abnormal family or home conditions	9	2	6	9	

In 1 case, antabus® was given to a 60 year old man (not included in this material) in the middle of a heavy drinking period. He apparently tried to conquer his uneasiness by drinking enormous quantities. He finally became unconscious and was brought to the hospital. Twenty hours after he had stopped drinking, his blood alcohol level was still 140 mg. per hundred cubic centimeters (blood acetaldehyde measured 1.3 mg.), and eight hours later his blood alcohol was 40 mg. (blood acetaldehyde was 0.3 mg.). The next day, he collapsed and died. This experience shows that it is inadvisable to treat such patients as outpatients. They require hospitalization, and medication should not begin until all alcohol has disappeared from the body.

Table 2.—*Effect on Various Groups of Patients with Alcoholism After Six Months of Treatment with Antabus®*

	Socially Re- covered	Much Better	Some- what Better	Un- changed	Total
I. Patients treated earlier without effect *	23	10	8	9	50†
II. Patients previously fined or jailed because of law violation in connection with alcoholism ‡	19	7	4	7	35§
III. Other patients	21	7	4	4	36

* Twenty-one patients received aversion treatment; 4 were treated by the aversion method and suggestion, and 25 were under hospital care or internment.

† Twenty-four of these patients also belong to group II.

‡ Seventeen were convicted of drunkenness in public places; 5 of theft, 12 of driving while drunk, 2 of fraud and 5 of disorderly conduct, while 5 patients had committed several offenses.

§ Twenty-four of these patients also belong to group I.

No absolute contraindications have been seen thus far. The referred Swedish case indicates that some caution is necessary in persons with heart failure. Among our patients, we have several with cirrhosis, arteriosclerosis, diabetes or stomach ulcers. The treatment has not had any vicious effect on any of them. The intensity of the reaction is not diminished as a result of continued treatment, as often occurs in the Voegtlin or the suggestive treatment. On the contrary, the reaction increases during medication or when it is begun again after a lapse of time.

PSYCHIATRIC APPROACH

Besides the medical treatment (which effectively stops the alcohol consumption), the patients have been submitted to intensive psychotherapy, aimed at mental and social rehabilitation. With modifications introduced by a drug which effectively prevents the patients from drinking, the psychotherapeutic methods do not deviate in principle from those hitherto used. Therefore, only a few points will be mentioned which have proved to be of special importance to the treatment. As can be seen from table 1, a regular intake of the tablets is essential for successful treatment. Therefore, the first effort is to accustom the patient to take his medicament regularly. Here a member of the patient's household, preferably his wife, can be of much help in making the patient feel that the intake of the tablets is a routine procedure in his daily life. The tablets can be presented at the breakfast table quite as naturally as the coffee and the morning paper. The physician must see the patient at regular intervals, and the next interview must be set every time. If the patient breaks the appointment, the physician must call him and ask the reason.

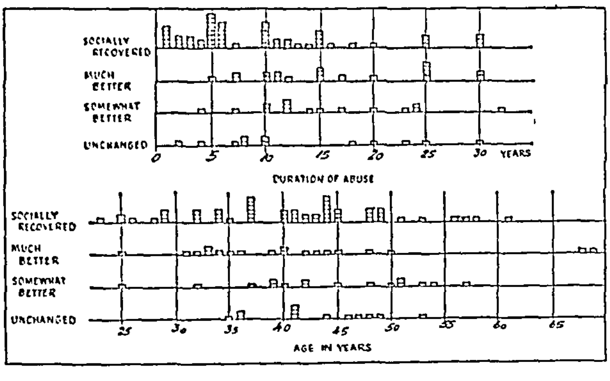
As to the final prognosis, it is of utmost importance to induce the feeling in the patient that he is really sick and in need of treatment. He should be told that just as persons with diabetes must avoid sugar, so he must avoid alcohol and use antabus® as his insulin. He must be informed that his constitution is such that for him alcohol is a poison.

Group Therapy. — Group therapy has proved extremely useful from the very beginning. In the sanatorium, the older patients follow with interest the newcomer's vain attempts to drink alcohol and even encourage him to experiment now and again. After a few days, this patient regards the new patients with the same interest and sympathy with which he was regarded. During this time, the patients may discuss their problems freely with each other. Early in their treatment, they have the opportunity to assist others, which gives them the self confidence to conquer the inferiority complex that is pathognomonic to most persons with alcoholism.



Graphs showing the influence of the age of the alcoholic patient and the duration of abuse on the results obtained on treatment with antabus.®

For continued treatment, an association "Ring i Ring," on the pattern of Alcoholics Anonymous, has been formed. Here the members have the opportunity to fill in the gaps in their lives which remain after they begin abstinence. The fate of their fellows can be an encouragement or a warning to them. Finally, the mutual support is of paramount importance in this association, as in all other groups of this kind.

Physical Rehabilitations.—Physical rebuilding has been sustained with administration of vitamin B preparations and insulin in some cases. Even without this, it is astonishing how little time is required for the patient to conquer his tremor and his morning vomiting and to regain his appetite. Often, the patient is physically restored within one or two weeks.

PRESENT MATERIAL

From December 1947 to May 15, 1948, 104 patients asked for treatment for alcoholism. A few were treated in the clinic of the Frederiksberg Hospital, Copenhagen. Eight of the patients were women. All patients were submitted to the antabus® treatment. Four patients were unable to be contacted after two to three months of treatment. One patient died of a cerebral hemorrhage after three months of treatment; 99 could be followed for six months, and 42 of these for nine months. The age of the patients and the degree of their alcoholism are given in the tables.

RESULTS

The results were due to the combined use of the medicament and psychotherapy and are given in the tables. In these tables, the following terms are used: "Socially recovered" designates a patient who can competently perform his work and live in harmony with his family. He may have relapses, but they are few, do not last more than twenty-four hours and do not influence his work or his family life. "Much better" designates a patient who can perform his work with integrity and who has had a few relapses that have not disturbed his social status. "Somewhat better" designates a patient that is somewhat improved but is subject to attacks which influence his work and/or his family life. "Unchanged" designates a patient in whom no real improvement has been noted. All these judgments are based on the statements of relatives, and, in some cases, after personal and repeated inspection of the patients' homes.

The condition of the patient after six months of treatment, the readiness with which he takes the tablets and the attitude of the relatives are given in table 1. It may be seen that the results are best when the patient readily and steadily takes the tablets and when the relatives are understanding. The figure shows the influence of the age of the patient and the duration of abuse on the results obtained. In table 2, the patients are placed into groups according to their past lives. As is to be expected, patients who were previously treated without effect show worse results than the group not previously treated.

Table 3 groups the material according to psychiatric diagnoses. These diagnoses are independent of the patient's attitude to the treatment. Patients with more or less pronounced psychiatric symptoms (signs of psychoneurosis or a manic-depressive state) are more difficult to treat than the psychically normal patient. Of course, the terms refer only to the alcoholism of the patients. If a patient is termed "socially recovered," it means only that he has stopped drinking. His mental disorders generally remain and present new problems to the psychiatrist.

The results after three months of treatment are not much altered during the next three to six months. In a few cases, there may be both improvement or the opposite, but a patient who is socially recovered after three months of treatment has an 85 per cent chance to remain socially restored after six months of treatment. The results after nine months are about the same as after six months, but the figures are too small to permit definite conclusions. Table 4 gives the results after three, six and nine months of treatment.

TABLE 4.—*Status of Persons with Alcoholism Six Months After Institution of Treatment with Antabus® Compared with Status After Three and After Nine Months*

	Socially Recovered	Much Better	Somewhat Better	Unchanged	Total
Status after 6 months	52	19	12	16	99

* The same 2 patients.

In this treatment, relapses do not play the serious role as in other treatments of alcoholism. Relapses are seen in patients who have stopped medication or who are treated with too small doses. After four to eight weeks of treatment, a number of patients are convinced that they are cured and never will taste alcohol again and therefore stop medication. Sooner or later, such patients will be tempted to take a "single" drink with the well known results. If such patients are still under observation, it is easy to stop the relapse in a day or two by means of renewed or increased medication. Generally, no serious damage is done. Often the accident will convince the patient that his optimism was unfounded and that he has to take his medicine for a long time. In these cases the relapse has fulfilled an instructive purpose. In cases in which the patient has stopped medication because he has no serious conception of his disease, it can be extremely difficult to keep him under control. Of course, his relapse can be cut short just as easily as in all other cases, but it will soon be followed by other relapses. Much patience is required on the part of the physician, relatives and friends to prevent such a patient from slipping out of control gradually.

Our experience is still too small to decide how long the patients must continue medication. Twenty-eight patients had no relapses during six months of observation, but only 11 of these continued medication that long a time. The others discontinued use of the drug after a longer or shorter time. Two patients stopped taking it after one month, and about half of the patients stopped after four to five months. It is, of course, necessary to follow these patients a long time and resume medication in case of relapse.

COMMENT

It is absolutely necessary to keep the patient under control for a long time, even after the cessation of medication. The patient still has the intolerance to alcohol which is characteristic of persons with alcoholism, and, regardless of how recovered they may feel, he always runs the risk of temptation. Experience has shown that even though the patient asserts his readiness to be cured at the beginning, it requires great effort on the part of the physician and relatives to encourage him to continue medication for a sufficiently long time. He is often inclined to take "holidays" in connection with approaching major parties. It must be explained to the patient that this procedure is wrong and will only result in more "holidays" and shorter intervals between. Antabus® is cheap and easy to administer, but it is also easy for the patient to discontinue treatment, thinking that he readily can stop drinking again by resuming medication. For this reason, the antabus® treatment offers new and difficult problems for the therapeutist.

Finally, we need not emphasize that six to nine months is an extremely short observation period to evaluate the final results for a cure for alcoholism. Nevertheless, we find antabus® promising and are convinced that, if properly used, it may be of value in the difficult task of treating persons with alcoholism.

SUMMARY

Alcohol given to persons previously treated with tetraethylthiuram disufide (antabus®) produces a series of disagreeable symptoms, which are the result of an increased concentration of acetaldehyde formed from alcohol in the organism. The symptoms are generally so severe that they prevent persons from taking alcohol. As long as the patients take the tablets, they will not drink.

Ninety-nine persons with alcoholism were treated with this substance and observed six months or more. After six months of observation, 52 can be regarded as socially recovered and 19 as much better. The medication must be combined with intensive psychotherapy in order to obtain permanent results.

Clinical Notes, Suggestions and New Instruments

CEREBRAL THROMBOSIS PRECIPITATED BY INJECTION OF A MERCURIAL DIURETIC

HENRY I. RUSSEK, M.D.
and
BURTON L. ZOHMAN, M.D.
Staten Island, N. Y.

Serious untoward effects from the use of mercurial diuretics in congestive heart failure have been relatively rare. Although some immediate fatalities have been reported from the intravenous use of these agents, it is generally recognized that the incidence of such reactions must be extremely low. Nevertheless, routine administration by the intramuscular route has been advocated as a means of preventing fatalities of this type.

Regardless of the method of administration, however, severe diuresis occasionally causes weakness, anorexia, mental confusion, apathy, restlessness, delirium, hallucinations and more rarely coma and death. It has been observed, moreover, that such manifestations of dehydration, which generally develop six to twelve hours after injection, are more prone to arise in the elderly patient.

In analyzing the toxic reactions to mercurial diuretics encountered at the United States Marine Hospital, Staten Island, during the past ten years, we observed a side effect heretofore not reported, namely, cerebral thrombosis. It had been the custom to inject 2 cc. of the diuretic intravenously in all cases in which the drug was used. No immediate serious reactions were encountered. In 3 patients, however, hemiplegia developed eight to fourteen hours after injection. Each of these patients was over 70 years of age. Two had hypertensive heart disease, one with sinus tachycardia and the other with auricular fibrillation. The third had calcareous aortic stenosis with sinus rhythm. All were in a stage of moderate congestive failure. In all of the patients there was a precipitous fall in the blood pressure following profound diuresis. The course was progressively downhill, with termination in one to three weeks. Two of the patients came to autopsy, and in each a fresh thrombus was found at the site of atheromatous degeneration in the left middle cerebral artery.

COMMENT

It is acknowledged that hemiplegia may arise from various causes in the elderly subject with congestive heart failure. Indeed, diminished blood flow to the brain in circulatory failure may in itself precipitate cerebral thrombosis. Embolization to a cerebral artery, particularly when auricular fibrillation has been present, as well as cerebral hemorrhage, cannot be excluded on purely clinical grounds. In the cases studied at necropsy, however, neither of the latter conditions was observed. The development of cerebral thrombosis eight to fourteen hours after an injection of a mercurial diuretic which caused extreme diuresis and fall in blood pressure strongly suggests a causal relationship in these cases. Excessive diuresis with or without a lag in the mobilization of tissue fluids undoubtedly may lead to appreciable decrease in circulating blood volume, cardiac output, systemic blood pressure and cerebral blood flow. It is conceivable that fresh coronary thrombosis may be precipitated in a similar manner when there is underlying coronary disease.

Experience in the handling of cardiac conditions soon teaches that the dosage of the mercurial diuretic, like that of digitalis, must be tailored to fit the patient. Not infrequently, 0.75 cc. is found to produce the desired effect without the weakness, prostration, muscle cramps and other symptoms which frequently follow larger doses. The routine use of 2 cc. for a first injection, whether given intramuscularly or intravenously, should be discouraged, particularly in elderly subjects.

Published with the permission of the Surgeon General, United States Public Health Service, Washington, D. C.

Director of Cardiovascular Research (Dr. Russek) and Consultant Cardiologist (Dr. Zohman), United States Marine Hospital, Staten Island, N. Y.

SUMMARY

Cerebral thrombosis with hemiplegia appeared to be precipitated by the injection of a mercurial diuretic in 3 elderly patients with congestive heart failure. This complication followed profound diuresis and fall in blood pressure resulting from excessive dosage of the drug. Coronary thrombosis could conceivably be caused in similar manner when there is underlying coronary disease. The routine use of 2 cc. of a mercurial diuretic for a first injection should be deprecated, especially for patients of advanced age.

Council on Physical Medicine

The following statement has been prepared by Dr. Charles S. Wise of the Department of Physical Medicine, George Washington University, and Chairman of the Committee on Cooperation of the American Congress of Physical Medicine with the Food and Drug Administration, as a result of conferences at the annual meeting of the American Congress of Physical Medicine. It has been reviewed by officials of the Food and Drug Administration, who have offered no adverse comment, and has been approved by the Council on Physical Medicine. HOWARD A. CARTER, *Secretary.*

A GUIDE FOR LABELING OF INFRA-RED HEATING DEVICES

With the establishment of physical medicine as a recognized medical specialty, qualified physicians in this field must assume some responsibility in the protection of the general public from false or misleading claims made in conjunction with devices which are becoming increasingly available. The Council on Physical Medicine of the American Medical Association is responsible for censorship of such claims made in regard to physical devices primarily intended for sale to physicians. The Food and Drug Administration of the Federal Security Agency, moreover, has the responsibility for protecting purchasers from misbranded or dangerous devices and drugs. The excellent progress already made in the field of drug therapy regarding high standards of labeling and accurate allowable therapeutic claims is largely due to the expert assistance which has been accorded the Food and Drug Administration by the various medical specialty groups. It is to be hoped that similar high standards for labeling and therapeutic claims for physical devices might be obtained through the provisions of the Federal Food, Drug and Cosmetic Act and the counsel and advice of specialists in physical medicine.

An immediate problem at hand has arisen through the widespread distribution and use by the lay public of infra-red heating devices. Many of the reputable manufacturers of infra-red heating lamps have continued to maintain high standards in their labeling and therapeutic claims in connection with their products, and it is expected that they will continue to maintain these high standards. Unfortunately, however, the general public is being continuously bombarded by advertising and labeling from manufacturers of heating lamps in which a host of therapeutic claims are made, many of which are open to serious question. Aside from being marketed with false and misleading therapeutic claims, many of these lamps are not supplied with adequate directions for use, and the inherent dangers of indiscriminate use of heating devices are obvious to the trained physiatrist. In view of this serious situation, the Committee on Cooperation of the American Congress of Physical Medicine with the Food and Drug Administration, in conjunction with the Council on Physical Medicine, has attempted to set up a minimal guide for labeling of infra-red devices based on the medical facts available from experts in this field.

It is the consensus among physiatrists that infra-red heating is in no way a specific therapy. It is felt that such standards as are applied to nonspecific drugs regarding therapeutic claims should also be utilized as a model for therapeutic claims for infra-red heating devices sold generally. For example, in the sale of such drugs as acetylsalicylic acid, or other nonspecific analgesics, the Food and Drug Administration regards as appropriate the claim "For relief of minor muscular aches and pains." It is felt that additional reference to specific disease entities for infra-red heating devices would lead to inappropriate use by lay purchasers in the belief that the device is a treatment for the underlying cause of the disease rather than beneficial only as a palliative. In addition, the inherent dangers associated with self diagnosis and self treatment in serious disease conditions would be involved.

It was also the consensus of the committee and other physiatrists consulted that the use of the terms "penetrating" and "deep" used in the labeling of infra-red heating devices is definitely misleading. When these terms are employed in conjunction with therapeutic claims for relief of muscular aches and pains, experience shows that the uninformed general public is misled into the belief that this radiation penetrates to the site of the involvement. Although it is well known that certain portions of the infra-red spectrum can pass through tissues to a greater extent than others, the penetration even with the shortest infra-red radiation is measured in millimeters. In view of this degree of penetration, and since we have effective means for deep heating by diathermy, and since the term "deep therapy" is used in conjunction with roentgen radiation, where depths of many centimeters of penetration are obtained, it is felt that these two terms are misleading and should not be employed in the labeling of infra-red devices.

To insure maximum protection of the general public in the use of physical devices, it is essential that the labeling contain adequate directions for use and adequate warnings against misuse. In a survey of representative labeling of infra-red heating lamps it is apparent that many manufacturers fail to include adequate directions and precautions. The committee believes that adequate directions should include the minimum safe distance at which the lamp should be placed, in order to provide a comfortable warmth. It is also advised that adequate warnings should be set forth against the unattended use of infra-red heat for children, debilitated persons, over anesthetic skin areas or in the presence of poor circulation.

Such gross mislabeling of physical devices as exists today reflects poorly on the status of physical medicine as a responsible medical specialty. The physiatrist should assume the responsibility for lending expert counsel to the Food and Drug Administration in cooperation with the Council on Physical Medicine in its efforts to obtain suitable standards for labeling of all physical devices for sale to the general public.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

AUSTIN SMITH, M.D., *Secretary.*

ADRENAL CORTEX EXTRACT (See New and Nonofficial Remedies 1948, p. 364).

The following additional dosage form has been accepted:

THE UPJOHN COMPANY, KALAMAZOO 99, MICH.

Solution Adrenal Cortex Extract: 50 dog units per cc., 50 cc. vials. Each cc. contains not less than 50 dog units when assayed by the Cartland and Kuizenga method, in isotonic sodium chloride solution. Preserved with alcohol 10 per cent.

DIGITOXIN-U.S.P. (See New and Nonofficial Remedies 1948, p. 267).

The following dosage forms have been accepted:

S. F. DURST & COMPANY, INC., PHILADELPHIA 20.

Tablets Digitoxin: 0.1 mg. and 0.2 mg.

CARROLL DUNHAM SMITH PHARMACAL CO., NEW BRUNSWICK, N. J.

Tablets Digitoxin: 0.2 mg.

SATURDAY, APRIL 2, 1949

THE NATIONAL PHYSICIANS' COMMITTEE

For more than ten years the National Physicians' Committee has been a leader in the defense of the freedom of American medicine; its support has come largely from voluntary contributions of the medical profession and from many industries related to the provision of a high quality of medical service. Like every other person and agency that has become involved in what is essentially a political controversy, the National Physicians' Committee has been subjected to vilification and abuse, mostly by those who were offering to trade medical care for political prestige but, in some instances, also by those who should have been friends. Under the leadership, from the beginning, of Dr. Edward H. Cary of Dallas, Texas, the committee has mustered to the support of the medical profession great numbers of citizens who saw in governmental regimentation of medical care but the first step toward the destruction of the American democracy. On the Board of Directors of the National Physicians' Committee former presidents of the American Medical Association, presidents of state medical societies, members of the House of Delegates and many other medical leaders not associated with the American Medical Association have served without compensation and often even without payment of the expenses covering their travels. Their work has been done in the missionary spirit.

With the coming of the present federal administration, the controversy over insurance to cover the costs of medical care has moved into a new level of intensity. Associated now with the promotion of this legislation by Wagner, Murray and Dingell and others leaning far to the left in governmental affairs, such as Senators Taylor, McGrath and Pepper, are misguided philanthropists and ambitious politicians who are using the vicious technics of propaganda to produce disaffection in the American Medical Association, distrust of medical leaders and enmity for the medical profession as a whole. Fortunately the prestige of scientific medicine the United States is so high that even this campaign could not injure it. Fortunately most American people are trustful of their individual doctors. This campaign can do them little harm. However, as was emphasized by Dr. Frank F. Borzell, Speaker of the House of Delegates, in a recent communication, the technic of the opposition has been the old "divide and conquer" formula. Surely the physicians of this country who are in a preponderant majority opposed to governmental regimentation of medical practice will recognize the nature of the campaign that is being waged.

No one asserts or claims that leadership in American medicine has not on occasion made mistakes. No one claims that every decision by the National Physicians' Committee has been perfect. No one claims even that the House of Delegates has not on occasion been slow to change its point of view. But medical leadership does claim that physicians must have evidence of the desirability of new methods and new technics in the delivery of medical service before it can act for the medical profession of the nation in accepting any proposal. Indeed, the great hazard of all such legislation as that which perpetrated the National Health Act on the people of Great Britain is the difficulty of eliminating such a procedure even after its faults have become horribly obvious. Better to delay in the interest of safeguarding the public health than to be pushed for public favor into a position from which there is no retreat.

When the National Physicians' Committee was first proposed as an agency to carry the campaign, its existence was justified by the statement that new times demand new technics. Today when the leader of a new federal administration throws the entire force of his position and his administration behind governmental medicine, the new approach adopted by the House of Delegates was the voluntary assessment of the membership of the American Medical Association in support of a far more powerful process of education of the people on this subject than has ever previously been possible. The medical profession has responded wholeheartedly; already enough funds are in hand to meet the budget of the first year.

Obviously the next question must be as to the future of the National Physicians' Committee. What that future is to be will depend on the decision of its own board of directors, since the organization has not been in the past and is not now in any way bound by the American Medical Association. No doubt its directors will continue to give their utmost support to the cause of freedom for American medicine; no doubt the agencies that have supported its work in the past will decide to continue if not increase their support to this cause under the stress of the intensified threat. The National Physicians' Committee has rendered an important service and has had the approval of the House of Delegates of the American Medical Association.

PENICILLIN FOR ORAL PROPHYLAXIS OF VENEREAL DISEASE—A WARNING

In October 1948, Eagle[1] reported the results of a study conducted in a Naval activity which showed that 100,000 to 250,000 units of penicillin by mouth, taken after exposure to venereal disease, would reduce the incidence of gonorrhea by 85 per cent or more. Following the publication of this report came strong pressure for general adoption of this measure. A second study conducted in the Navy[2] indicated that the prophylactic effect of orally administered penicillin on gonorrhea diminished fairly rapidly with the increase of time between exposure and ingestion of the penicillin. After an elapsed time averaging fifteen hours between exposure and prophylaxis, the efficacy of the measure apparently dropped to less than 50 per cent.

The Navy does not contemplate general adoption of this prophylactic measure against venereal disease. First, the method will presumably not protect against chancroid, lymphogranuloma venereum or granuloma inguinale, diseases which are of importance in many areas of the world. The efficacy of the measure against syphilis is not known and can be determined in man only after long and careful studies involving hundreds of thousands of individual uses. A long time must elapse before the reliability of this procedure as prophylaxis against syphilis can be established. Estimates indicate that a cost of approximately $75 per case of gonorrhea prevented at one of the Navy's largest prophylactic stations would have been incurred,[3] had oral prophylaxis with 250,000 units of penicillin been added to the standard Navy prophylaxis. This cost would of course diminish in proportion to the increased risk of contracting gonorrhea which exists in certain foreign ports, and the measure might approach economic justification in certain selected localities. The mass use of penicillin orally for prophylaxis of venereal disease will probably be adopted by the Navy, if at all, only for certain selected areas and periods when risk of contracting venereal disease in a particular group is abnormally high. The procedure will not of course be recommended as the sole prophylactic measure.

The use of penicillin orally by persons not in armed forces will be a matter for individual decision, if the tablets are made available over the counter. For those who do not use prophylactic measures or whose skill or knowledge are insufficient to use known effective measures properly, and possibly for women, this method offers for the time being a valuable protection to health. The method can be demonstrated to be economically unsound, since scores of tablets would be taken in order to prevent a single attack of gonorrhea in most American cities.

The measure presents a potential hazard of great magnitude to the venereal disease control programs of public health agencies. Some laboratory evidence indicates that the tendency of the gonococcus to become resistant to penicillin is much less than its tendency to become resistant to sulfonamide compounds. The resistance to penicillin is rather easily lost. After a failure of cure with a given dose, the same dose on a later day may sometimes effect a cure.

One reason that penicillin-resistant strains of gonococci have not become prevalent in this country is believed to be that the standard dose of penicillin used in treatment in this country is several times the minimal curative dose. Usually the dosages used will cure all but 1 or 2 per cent of the cases in the first course of treatment. This excessive dosage will kill off promptly almost all mutant strains that have developed only moderate resistance. Occasionally as much as 900,000 units of penicillin is needed to obtain a cure in gonorrhea.[4]

Considering that blood levels obtained by oral administration of penicillin are only a small fraction of those obtained by the standard parenteral treatment for gonorrhea, the general adoption of oral prophylaxis against gonorrhea might eventuate in a large number of persons' harboring gonococci and receiving frequent subcurative doses of the antibiotic. This new situation would be ideal for production and propagation of resistant strains of gonococci. Although the possibility is as yet only a question, the general use of penicillin orally for the prophylaxis of gonorrhea might hasten the day when 1,000,000 units of penicillin will be required to cure an average case of gonorrhea.

ROLE OF THE HOSPITALS IN MEETING NEED FOR PHYSICIANS FOR THE ARMED FORCES

The Council on National Emergency Medical Service of the American Medical Association held a conference in the headquarters office recently with a view to determining procedures to be followed in obtaining the physicians immediately required by the armed forces. The response to registered letters sent by Mr. Forrestal to all young physicians trained under the A.S.T.P. and V-12 programs who had not yet had military service was quite inadequate. Apparently but few of these young men are impressed with their responsibility in the present emergency. Most of them are of course at present engaged in residencies, which apparently they do not wish to leave. The Army, Navy and Air Force require more than two thousand doctors to take the place of physicians whose two year service periods expire by December 31. Replacements must be available, preferably by that time. The proposal has been made that hospitals from now on give credit in making their appointments to residencies to those young physicians who have had military service. In competitive examinations such credit may well be the determining factor in making the appointment. Unless the response is sufficient to meet the need, the federal government will unquestionably have to secure these young men by draft, and the Association will certainly not be in any position to oppose such draft.

---

[1] Eagle, H.; Gude, A. V.; Beckman, G. E.; Mast, G.; Sapero, J. J., and Shindledecker, J. B.: Prevention of Gonorrhea with Penicillin Tablets. Public Health Rep. **63**: 1411-1415 (Oct. 29) 1948.

[2] Campbell, V. W. H.; Dougherty, W. J., and Curtis, C. E.: Delayed Administration of Oral Penicillin as Prophylaxis for Gonorrhea, to be published.

[3] Because of recent reduction in the cost of penicillin to the Government this figure would perhaps be approximately $30.

[4] Parkhurst, G. E.; Harb, F. W., and Cannefax, G. R.: Penicillin Resistant Gonorrhea vs. Non-specific Urethritis. V.D.I.: **28**.. 211-213, Oct. 1947.

Many men in this group are deterred from accepting reserve commissions by contracts with hospitals for residencies. Hospitals should review the contracts that they have made for the next year. In the instances in which they have contracted with men who have not had military service they should discuss the possibility of deferring the date for fulfilling the contract and hold the residency available until the physicians concerned have completed their period of service in the armed forces; this period will be two years. In the interval hospitals should easily obtain temporary replacements, by utilizing the services of physicians who have completed their military service.

Current Comment

A STATE PROGRAM AGAINST CANCER

The Illinois Division of the American Cancer Society has mailed a letter with the approval of the American College of Surgeons, the "Downstate" Projects Committee, the Medical and Scientific Committee of the Illinois Division and the Cancer Committee of the Illinois State Medical Society to the president and the secretary of each county medical society. The letter stresses a growing demand by the public for a physical examination which would aid in early detection of cancer. The establishment of cancer detection centers would be difficult, and it has been suggested that "every doctor's office act as a Cancer Detection Center." The following minimal examination may be performed in each doctor's office. This examination would include a history to elicit possible symptoms of cancer, examination of the various orifices, examination of the skin and palpation of lymph nodes, blood pressure, examination of heart and lungs by percussion and auscultation, careful examination of the female breast, abdominal palpation, bimanual and visual pelvic examination in women and digital rectal examination to include prostate in men, and also urinalysis. Vaginal smear study, complete blood examination, roentgen examination of the chest and the like could be eliminated as a routine procedure. The authors of the letter felt that this plan would benefit the medical profession by improving medical public relations. Although limited in scope, the proposal is the first cooperative effort of its kind developed for the medical profession of Illinois.

MICROWAVE RADIATIONS

Osborne and Frederick[1] have studied the effects of microwave radiations on the living tissues and particularly on the eye. The radiations were formed by the Raytheon® microtherm which generates energy in a continuous wave, air-cooled magnetron oscillator tube, the first generator of this type to be developed for the heating of human tissues. The microtherm operates at a frequency of 2,400 to 2,500 megacycles or at a wave length of approximately 12 cm. with a maximum power output of 125 watts. After exposure of thighs of dogs to high frequency energy, the maximum temperature was observed in the subcutaneous level and decreasing temperatures were found with increasing depths. The average temperature at a depth of 2 inches (5.1 cm.) from the skin surface was 104.1 F. In 7 "acute" experiments on dogs the eye was exposed to microwave radiations. The average temperature of the vitreous body following microwave treatment was 105.8 F. One animal received a series of six treatments over a period of three weeks. Evidence of damage to the eyes or contiguous tissues did not appear. In twenty-four experiments on human subjects the thigh was exposed to microwave radiations. The average temperature at a depth of approximately 2 inches immediately following irradiation was 104.2 F. One small superficial blister was produced. The treatments were comfortable to the patients and a minimum of erythema was noted. Worden and his associates[2] report experiments on the temperatures of the skin, subcutaneous tissue, superficial muscle and deep muscle of the thigh of the dog after exposure to microwaves with the circulation intact and after ischemia produced by clamping the abdominal aorta. The temperature rises in the ischemic tissues were slightly higher than in normal tissues but were not considered significant after five or ten minutes of exposure, nor was there any evidence of burning after exposure for these shorter periods. After fifteen to twenty minutes of exposure the increased temperatures in ischemic tissues were considered significant with gross evidence of burning in most of the animals. The authors conclude that temperature tolerated by normal tissues cannot be regarded as the safe range of tolerance for ischemic tissues. Bony prominences were potential sites for formations of blebs. Richardson and his associates,[3] utilizing the Raytheon® microwave generator, produced cataractous lenticular opacities in rabbit eye after a direct single exposure. The average temperature of the vitreous in this experiment was found to be 55.1 C. at the posterior pole of the lens, while that of the cornea was found to be 49.4 C. A series of repeated exposures of a smaller magnitude resulted in cataractous lenticular opacities after a delay of two to forty-two days. Until further data are accumulated, precaution should be observed in the use of microwaves in the region of the face and orbit.

ORGANIZATION SECTION

Washington Letter

(From a Special Correspondent)

March 28, 1949.

A. M. A. Leaders and Secretary Krug Plan New Medical Missions

Secretary of the Interior Krug conferred on March 24 with leaders of the American Medical Association on cooperative sponsorship of new medical missions. These will be undertaken, probably first in Alaska and on Navajo-Hopi reservations of the Southwest, as a result of the success which attended the eight medical surveys conducted in 1947-1948 under similar auspices. The new program, however, will concern itself with medical care and advanced instruction of Indian Bureau doctors, the task of surveying the needs having been completed. The American Medical Association again will have the responsibility of selecting teams of specialists to go on the missions. It is expected that the first will be sent out this summer, probably to Sitka, Alaska. Attending the March 24 conference were Drs. R. L. Sensenich, Ernst E. Irons, George Lull, Morris Fishbein, Ernest B. Howard, James R. Miller, Elmer L. Henderson, Louis H. Bauer, Edwin S. Hamilton, Joseph Lawrence, William A. Morgan and R. Lyman Sexton.

During April and May, the Bureau of Indian Affairs will make an effort to administer BCG vaccination against tuberculosis to all Indian children who are shown by test to be unexposed. Eight teams, each comprising a physician, a public health nurse and a recording clerk, will give the vaccinations in the following states: Arizona, Colorado, New Mexico, Utah, Idaho, Montana, Nebraska, North Dakota, South Dakota and Wyoming.

Hearing on Veterans Hospitals Nears Close

Protests against proposed retrenchment of the Veterans Administration hospital construction program were heard by a special Senate subcommittee during the week ended March 26. A supplementary statement presented by the American Hospital Association and a factual report by the Oklahoma State Medical Association were among the few documents added to the hearing record which did not criticize President Truman's executive order to eliminate or reduce the size of thirty-eight new hospitals for veterans.

John H. Hayes, superintendent of Lenox Hill (New York City) Hospital and chairman of the Council on Government Relations, American Hospital Association, filed a statement emphasizing that the veterans hospital program exceeds the need of service-connected cases. Dr. Austin H. Bell, representing the Oklahoma State Medical Association, presented statistics on availability of physicians, dentists, nurses and auxiliary personnel in his state, leaving it to the Senate subcommittee to decide whether their numbers are sufficient to permit adequate staffing of veterans hospitals in Oklahoma. According to his testimony, the state has 2,266 licensed practitioners of medicine, 752 dentists, 3,513 registered nurses, 210 registered laboratory technicians, 71 registered x-ray technicians, 20 registered physical therapists and nine registered occupational therapists.

Surgeon General Appeals for Restoration of Budget Cuts

Dr. Leonard A. Scheele, Surgeon General of the U. S. Public Health Service, went before the Senate Appropriation Committee on March 24 to appeal for restoration of funds which had been eliminated by the House when it passed the agency's budget for 1950. Principal items at issue are: general assistance to the states, control of communicable diseases, expenses for administration of the Hill-Burton hospital construction act, a special vital statistics project and water pollution control.

Chief emphasis was placed by Dr. Scheele on the need for appropriating the full amount of $24,408,000 which was approved by the Budget Bureau for assistance of local public health units, immunization programs and other forms of aid to the states. This figure was trimmed to $13,600,000 in the House-passed bill.

"State health officers have given us their positive assurance that the entire amount contained in the President's budget is essential and can be utilized effectively at this time," said Dr. Scheele. "The program of general assistance to the states is the backbone of expanding federal-state cooperative activities in the field of public health."

The other reductions which he asked the Senate to restore were $250,000 for communicable disease control, notably malaria and typhus work in endemic areas; $400,000 for expenses of administering the Hill-Burton act; $295,000 for a vital statistics project, one phase of which is a test of the completeness of birth registration, and $380,000 for administration of the water pollution control act.

Enactment by the Senate of the appropriations bill is expected in April. The measure then will be sent to conference, where differences between the House and Senate will be ironed out and compromises effected.

Lodge Bill to Provide "Free" Drugs Reintroduced

A federal-state program designed to raise health standards and give economic relief to patients who are medically indigent has been proposed again by Senator Henry Cabot Lodge Jr. (Republican, Mass.) His bill, S. 1106, is identical to the one he submitted in the last session of Congress. Drugs, roentgenologic services, laboratory diagnostic services and respirators would be made available without cost to the patient when the need for such aids was certified by a local administrative authority, by terms of S. 1106. One half the cost would be borne by the federal government. Eligibility of applicants would be determined locally rather than by the Surgeon General of the Public Health Service, who would have general supervision of the program.

Other legislation introduced the first week in March included bills that would further liberalize provisions of the Hill-Burton Act; establish a Federal Commission on Services for the Physically Handicapped and amend the Food and Drug Act to provide for certification of drugs composed wholly or in part of aureomycin, chloramphenicol (chloromycetin®) or bacitracin.

British Health System Described by Dr. Davis

The February 11 issue of *Public Health Reports,* weekly publication of the U. S. Public Health Service, consists mainly of a detailed account of the organization of the British National Health Service, which became effective on July 5, 1948. The author is Dr. Burnet M. Davis, of the Division of Public Health Methods, U. S. Public Health Service. He is a son of Michael M. Davis, executive director of the Committee for the Nation's Health.

"No attempt is made to pass judgment on either the desirability or feasibility of the program, or to appraise its operation," Dr. Davis says in the article's introduction. The account covers 30 printed pages.

Veterans Administration Designates 5 Medical Substations

Atlanta, Boston, San Francisco, St. Louis and Fort Snelling, Minn., have been announced by Veterans Administration as key positions from which medical supervision of hospitals will be performed. Their selection follows elimination of the Veterans Administration's branch office system, which provided for a chief medical officer at each of the thirteen branch offices. Their former functions are now centered in Washington.

Hoover Commission Favors Science Foundation

Establishment of a National Science Foundation is recommended by the Hoover Commission in a three part report on federal research transmitted to Congress on March 25. The science foundation bill already has been passed by the Senate, and House hearings on the question are scheduled for March 31, April 1 and April 4.

NATIONAL CONFERENCE ON RURAL HEALTH

Fourth Annual Meeting, convened at the Palmer House, Chicago, Feb. 4 and 5, 1948

DR. F. S. CROCKETT, Lafayette, Ind., *Chairman*, Presiding

FRIDAY FEB. 4, 1949

CHAIRMAN CROCKETT: Our first conference, as you know, explored the rural health situation in all parts of these United States. We came away with a truer picture of the rural needs and a better recognition of what it would take to cure those needs. The atmosphere of honest candor and friendly understanding set the pattern for these subsequent meetings. We hope we can continue on that broad friendly informative basis.

In our second conference, we employed the panel type of discussion with study of such subjects as how to get and keep medical personnel, especially doctors, nurses and dentists; hospital and diagnostic facilities; medical care for low income families, and prepayment plans for medical and hospital care. We reverted to the didactic type of program in our third conference. We paid tribute to rural youth, as eminent essayists gave us the benefit of their thinking. We learned that the tradition of the country as a healthful place to live was subject to some correction. We were told that the country was not better or worse than the city. Each, to be a healthful place *to live, must resort to well known health measures.*

This year we study the rural and farm environment. Life in the country is surrounded by many hazards; farm and highway accidents, animal diseases affecting human beings, depletion of the soil affecting nutritive crops, nutritive value of crops, and, since the war years, introduction of pestilence control in the use of chemicals not too well understood in relation to their poisonous qualities. This points to the preventive measures which local and state health councils must make.

Each year we continue to discuss rural needs in the light of the country doctor and community responsibility. It is a two way road and the trip must be made together.

Health programs of national organizations are an important part of this program today and are placed first in recognition of that fact. The American Medical Association has sought to work harmoniously with any and all groups interested in rural health. A number of other agencies have been active in this same field. They have all made valuable contributions to specific phases of the problem.

The plan of our committee is unity of effort. We are not *just conducting another plan.* We are *trying to get all the* other agencies, all other people that are interested in rural health, to join with us in a unified effort to reach the common objective. I am sure we have in the Community Health Council the mechanism for achieving unity of purpose and action and the avoidance of overlapping.

In forming the panel memberships we have tried this year especially to have persons who have never been on these programs before, leaders and other authorities who we felt had really new points of view and fresh enthusiasm. We have purposely left the members of our committee and our advisory committee free to mix with the audience and learn for themselves the strength and weakness of our present conference methods.

We have first the health programs for the national farm organizations. We have asked Mrs. J. Laning Taylor, Educational Director of the National Cooperative Milk Producers Federation of Washington, D. C., to present their program first.

Health Program of the National Cooperative Milk Producers Federation

MRS. J. LANING TAYLOR, Washington, D. C.: The National Cooperative Milk Producers Federation is a group of cooperative associations operating across the nation in forty-seven states and owned and controlled by the farmers themselves—some 425,000 of them. These associations fall into a number of categories. Some near large urban areas are primarily fluid milk bargaining groups. Others handle milk through their own facilities; from the farm to the consumer's doorstep. Many are engaged in manufacture of butter, cheese, evaporated milk or other dairy products. All are chiefly interested in marketing of milk, and all have interests and functions aside from marketing.

Health programs are basic to their business. All of us in the dairy industry are in a real sense purveyors of health. These foods require unusual sanitation in handling. They are subject to strict regulations in production and transportation and to rigid inspection. Laws and ordinances make it incumbent on dairy cooperatives to comply rigorously with basic health programs.

In each of the eighty-six member associations and the hundreds of submember associations there are well defined departments. The membership service department employs regular visitors to the farms of the individual milk producers. Their duties are to help individual farmers maintain quality production and farm sanitation. If anything goes wrong and an individual producer's milk falls below the prescribed standards, the field man is the trouble shooter. The field man's attention is directed to the utensils, the milk house and the barn equipment and the physical handling of the milk. It extends also to the herd. An association may have a full time veterinarian on its staff, or its field men may work with state, county or private veterinarians.

Membership service departments also advise and assist members through bulletins, motion pictures and meetings directed toward practical procedures in producing top quality dairy products. The purpose of membership services is twofold: (1) to assure the urban consumers of dairy products which meet or exceed the standards of quality set by local regulations and ordinances and (2) to assist the farmer member in meeting or exceeding these standards so that his milk and cream will net him a satisfactory return.

Dairy cooperatives place a great deal of emphasis on programs for quality production and farm sanitation. A questionnaire *survey shows that these programs account for 96 per cent of* the field staff's time. One of our larger organizations reports fifty-five dairy servicemen and thirty-four area managers.

Perhaps the most significant point to be derived from these and similar reports is the fact that where a rural health problem exists and where a plan is laid out to meet it, dairy farmers tackle it with a vengeance. They will go ahead on other rural health programs as they recognize the need, and as they clearly see the way toward accomplishment. The dairy farmer and his family have become health conscious, have learned the technics of farm sanitation and recognize the importance of disease-free herds. They know that although urban milk consumers are protected by milk pasteurization from bovine tuberculosis and brucellosis, they themselves are subject to bovine diseases communicable to man from drinking unpasteurized milk or from contact with diseased animals. They see the need for an all-out job in this direction.

Our questionnaire shows a wide support by dairy cooperatives of Farm Safety Week—by publicity, by articles, by posters, by efforts of field men, by contributions to the cost of advertisements in newspapers, and so on. Need and desirability of accident prevention has been recognized. The equally essential step has been the supplying of material by the National Safety Council.

In group hospitalization and health insurance projects large cooperative creameries and branches of large scale dairy cooperatives are probably the largest single group of cooperatives enrolled in Blue Cross. One of the large regional dairy associations, the Farm Credit Administration reports, has a program of hospital insurance with a commercial insurance company covering some 12,000 persons. These programs have been patterned so that they can be adopted and adapted by local rural groups.

Dairy cooperatives also promote and work with local health units, local health councils, and cooperative hospitals. They serve on local health boards. Others are members of hospital advisory councils. They support state and national legislation directed toward rural health programs.

While all dairy cooperatives are interested in some types of health program they are not all currently active in all phases of the broad rural health program. It is here that the local groups should be able to call upon the national organizations for assistance. The obligation of the National Cooperative Milk Producers Federation, the American Medical Association, and the general farm organizations is to ascertain and make available the patterns which can be most universally adapted to local rural health needs.

Today the health program of the National Cooperative Milk Producers Federation at the state and local levels is the sum total of the day to day and the month to month activities of its eighty-six members. Specific projects include:

(1) maintenance of quality milk production and farm sanitation; (2) elimination of bovine diseases, including those communicable to man; (3) participation in Blue Cross and other group hospitalization and health insurance plans; (4) quarantine insurance plans under which members are reimbursed for milk which is barred from shipment because of quarantine; (5) participation in Farm Safety Week; (6) promotion of soil-building programs, and (7) support of state and national legislation directed toward the elimination of animal diseases and the promotion of rural health programs.

The National Cooperative Milk Producers Federation on the national level recommended (1) the encouragement of prepaid medical, hospital and dental care on a voluntary basis, (2) federal aid to improve health standards through health education and research, (3) an expanding school lunch program and (4) support of federal-state programs for the control and eradication of bovine diseases.

Chairman Crockett. Mr. Joseph Fichter, master of the Ohio State Grange, Columbus, Ohio, will give us the health program of the National Grange.

Health Program of the National Grange

Mr. Joseph W. Fichter, Columbus, Ohio: The health program of the National Grange started about five or six years ago in an active way. The first unusual interest manifested by the National Grange was the result of a committee study and report in November 1943. As a result of that report, the organization worked out a stand on health in the form of resolutions. Since that time each succeeding year has seen resolutions adopted based on those of the previous year. Our farm people through their organizations are giving attention to the whole matter of health.

About five years ago a committee was appointed known as an interim health committee to carry out some of the things that were decided on at the annual session and to give thought to recommendations at the succeeding sessions. A committee of national scale was considered insufficient unless committees were established in state, county and local units. The organization appointed such committees. Not all the local units in the Grange throughout the nation have a health committee, but there are a large number.

Health committees have taken over the duties of our home economics committees. The home economics committees previously had health and nutrition as part of their task. It was felt, however, that the matter of health is so important that there ought to be a committee especially for that work.

We have meetings of our local granges every two weeks. During these meetings we have an educational program along with the business meeting, and the health committee presents something that ought to be discussed. Certain suggestions are made that arise in our national committee.

Last year we emphasized consideration of cancer and tuberculosis. This year we are going to include heart disease and mental health.

That is a broad outline of some of the things that we are doing in those fields. Increased emphasis needs to be given to the matter of diet and nutrition. If we get that we shall be able to save much money in all of the things that go to cure illness.

I should like to give you a summary of the action that was taken at our last National Grange Convention on the policy in rural health. Rural people should share fully in the benefits of modern medical science regardless of their economic status, race or geographic location, and to that end we recommend and are working for the improved accessibility and quality of hospital and medical facilities in rural areas with an increased number of well trained physicians in rural areas and a medical cost payment system which will enable all people to secure modern medical care without undue burden. Rural citizenry must be informed as to what constitutes adequate medical care and informed how it can best be secured. Adequate public health services and increased research in the various fields of health are necessary.

All the farm organizations feel that there is a shortage of doctors and health workers in rural communities. Yesterday we had the experience of having representatives from two of the groups, one of them from the Council on Medical Education and Hospitals of your Association and the other a representative of the Association of American Medical Colleges, who met with our rural health conference to bring to us the work that the Medical Association has done to increase the number of doctors and health workers in rural areas. We did not get the answer to the questions, but out of the discussion came this conclusion—that all of us in all of the fields lack information that needs to be supplied.

This experience we had yesterday is an indication of the value that can be obtained from constructive and mutual conferring as exemplified by this meeting today.

Health Program of North Dakota Farmers Union

Mrs. Lulu Evanson, Director of Education, Jamestown, N. D.: I will speak first on the national farm picture. We are working for a department of human resources, a secretary of human resources with cabinet standing, such as the Secretary of Agriculture, Labor or State. We spend millions every year for healthier animals and healthier lands, and we believe human beings should have the same consideration. We believe that insurance in health is necessary. We believe that it should contain the compulsory feature, just as we believe in compulsory education for our children.

We believe in the free choice of doctors and certainly that the doctors shall have a free choice of patients. We will continue to fight for local control of this program and that this national program shall provide for voluntary health programs.

We believe we should have scholarships, particularly for young men and women from rural areas who are unable to provide the money for education. We believe in federal aid for medical colleges so that they can provide training for more doctors, dentists, nurses and technicians. We should like to see changes in the Hill-Burton Bill, Hospital Construction Law No. 725. We should like to see eliminated the insistence that construction be let out on contract. We find in North Dakota that under contracts, cost of hospital construction is prohibitive.

In South Dakota they built a modern, up-to-date, eighteen bed hospital for $47,000. The same hospital in North Dakota, under contract and under the government program, will cost us from $285,000 to $300,000. If the people wish to donate labor it should be considered in the program; it cannot be under the present law.

Public health units are basic to a health program, and so we will continue to work for complete public health coverage not only for rural people but for the people in the small towns, for complete coverage in America.

We believe in our health workshops; we believe it is a way to get our people together with competent consultants at hand to study their health needs and to provide ways and means of meeting these needs.

We feel that environmental sanitation is vital in rural areas where so little has been done. We are asking for R. E. A. so that with electricity we may have modern facilities and sanitation.

One of the most vital steps forward is the preparation now of a study text on the relation of soil, plants and the general health of people. We have a triangle health plan—hospital, surgical and death benefits. We are developing a pilot cooperative clinic and hospital program to provide complete services for the insured under the triangle plan. We will continue our health education work, for we know that the welfare and security of the nation are tied closely to the health and welfare of its people.

Chairman Crockett: Mr. H. E. Slusher, Chairman, Medical Care Committee, will give us the Farm Bureau program.

Health Program of American Farm Bureau Federation

Mr. H. E. Slusher, Jefferson City, Mo.: The American Farm Bureau Federation held its thirtieth annual meeting in December 1948. The Bureau has a definite rural health program.

These are extracts from the 1948 resolution: Unfortunately, American medical service at its best reaches only a relatively small part of the rural areas of the country. The primary factors which most influence adequate medical facilities and which attract physicians are community environment and economic opportunity.

Rural people must first know their existing facilities and whether or not they are adequate. They must know the meaning of high standards in hospital and medical care. They must be taught the advantages of budgeting the costs of medical need as they do other household expenses. They must know the significance of health hazards around the farm home as they pertain to disease, including the relationship between animal diseases and human health. They must discover their own health needs and formulate their own program.

State farm bureaus must give serious consideration to the desirability and possibility of offering scholarships whereby physicians, surgeons, dentists and nurses will be encouraged to establish themselves in rural areas. We believe the problem of improved health can best be met by the voluntary organization of cooperative health associations which will encourage people to take advantage of the services available for any medical or dental care which they may require.

We favor voluntary plans providing medical, health, dental and hospital insurance. We urge that facilities of medical schools be expanded, and every effort be made otherwise to train more physicians, surgeons, dentists, nurses, technicians and general practitioners and public health doctors. We recommend the full cooperation of rural people with our established health units and existing health programs, including immunization, clinics, nutrition courses and home nursing. Greater emphasis should be given to preventive medicine. To the extent federal grants are needed by way of assistance, such grants should be made to states on the basis of need, with state governments responsible for the allocation and administration of these funds.

In the administration of the Hill-Burton Hospital Act and other similar acts, agriculture must have adequate representation on national and state advisory councils.

The health program of the American Farm Bureau Federation has been, first, education. Education means an awareness on the part of the individual that there is really a health problem. Cooperation with the medical profession has always been encouraged. State and county health councils have been organized. Cooperation in every way possible has been given to the state health departments.

Through the publicity department of the American Farm Bureau Federation and of the various state federations, support is given to the American Red Cross National Blood Program, Cancer, Tuberculosis, Venereal Disease, Poliomyelitis, Crippled Children, Heart and Rheumatic Fever programs.

Many of our state farm bureaus maintain full time health directors who cooperate actively with all state health groups. The bureaus sponsor Blue Cross hospital and Blue Shield medical-surgical programs. A few states have their own health insurance programs which are a part of their regular life insurance program. All of these programs are tied into the education activities of the organization.

The second step in the program is legislation. We suggest national legislation to help finance county hospitals and county health units on the basis of need. We feel that such programs should be on the basis of grants-in-aid and with a minimum of federal control. At the state level we assist in getting necessary enabling legislation passed to meet the requirements of the national legislation.

We have not recognized the need for or feasibility of a national compulsory health insurance program. Experience of such programs in England, Austria and Germany indicates that they have in no way solved the health problem. Such programs have aggravated the problem. The service and quality of medical care is much poorer than before the plan was put into effect. The integrity of the physicians is of a low standard, and medical service costs are extremely high in comparison with services rendered. Under such programs there can be no such thing as health insurance, and it is wrong in every sense of the word to tell the public that there will be.

The American Farm Bureau Federation still believes in the philosophy that the greatness of this country rests on the willingness of the individual to cooperate with his neighbor to find the solution to all his social and economic problems; that government should be for the people and not people "pawns" of the government.

Chairman Crockett: We will now proceed to the next subject on our program, "A State Rural Health Committee in Action," by Dr. DeTar, of the Committee on Rural Health, Michigan State Medical Society.

A State Rural Health Committee in Action

Dr. J. S. DeTar, Milan, Mich.: The paramount reasons for action by a state rural health committee are the same as similar action on a national level: disease among rural people, faulty nutrition, inadequate immunization, supply of hospitals and doctors, the high rate of mortality caused by accidents, the need for health education and the need of rural people to protect themselves against the financial hazards occasioned by sickness and hospitalization.

The need for action on the state level is of far greater importance than on the national level. And the need for action on the local community level outweighs the need on the state level. Until the rural people of America, including the farmers, the laborers, the civic leaders and the doctors, become sufficiently aware of the need for cooperative action on the local level it will be impossible for any action on a national and state scale to fulfill its purpose. Community health councils require and should have state leadership. The state health councils require and are getting help and guidance from this and the preceding three National Conferences on Rural Health.

Two years ago at the close of the meeting, a half a dozen persons from Michigan decided to plan a state rural health conference modeled after this meeting. Twenty state organizations were invited to participate. We asked the state medical society to finance the program. Two thousand dollars was appropriated for the first state rural health conference.

The Conference.—The first state rural health conference was held at the state capital. Sponsors included farm organizations, medical societies, universities, educational associations, health departments, pharmaceutical and nurses' groups, crippled children's and cancer societies, parents and teachers. The program included presentation of the health problems of rural people including hospital facilities, the problem of attracting physicians to rural areas, the financing of health programs, the need for nurses, the need for medical associates for a greater spread of the benefits of scientific advance, and the need for measuring more accurately the exact health needs of rural areas.

Preparation and execution of the program were done largely by the medical society. Conference talks and discussion were therefore slanted to the medical point of view. Physician participation overshadowed that of other groups. Every effort was made to provide multilateral participation, and the expression of opinion was stimulating. The main resolutions adopted by that first conference were: (1) a scholarship fund for medical students who would agree to practice in rural areas; (2) increased appropriations for our medical schools; (3) more local community health councils; (4) nurse recruitment among 4-H Club members, with assistance from local organizations, and (5) another conference the next year. This expression of opinion from three hundred persons from all over the state called for action.

Action.—1. Scholarships for Medical Students: A special fund was set up in a separate corporation called "The Michigan Foundation for Medical and Health Education." This foundation receives donations from all possible sources for educational purposes. To date, over $100,000 has been contributed to the foundation. Scholarships have been announced with provisions requiring practice in rural areas, similar to those in many other states. Opportunities and advantages of rural practice were presented by outstanding family physicians from small communities to medical students. Doctors who asked for information about rural areas were given a complete list of towns requesting physicians. Towns were informed of available doctors and their qualifications. To date, many additional physicians have settled in the rural areas of Michigan.

2. Increased Appropriations to Medical Schools: The legislature was persuaded to appropriate over $1,000,000 for a new maternity hospital at the University of Michigan. A committee was appointed by the state medical society to cooperate with the deans of the medical schools toward providing additional facilities and instruction.

3. More Local Community Health Councils: A local community health council in which farmers, and teachers and doctors and health specialists, could pool their efforts on a local level constituted the real essence of the problem. A State Health Council, with membership consisting of all state organizations interested in health, was organized. A board of trustees was elected. Twenty-two thousand, five hundred dollars was supplied by the state medical society and the Michigan Medical Service (Blue Shield) and Michigan Hospital Service (Blue Cross). An executive secretary was selected last month, offices were set up and work is progressing. The duties of the full time executive secretary will be to coordinate the work on a state level and assist local communities in the formation of their local community health councils which will have representation in the State Health Council. It appears that the results will justify the effort expended.

4. Nurse Recruitment: The aid of the woman's auxiliary of the state medical society was enlisted. A new committee of the state medical society called The Commission on Health Care was asked to investigate not only the need for nurses, but for associates of the physician in all fields, including the fields of dietetics, pharmacy, medical technology, physical therapy, roentgen technology and twenty-one other vocations associated with the practice of medicine. Eight thousand dollars was spent in this investigation and recruitment. Brochures were distributed to high schools, colleges and other interested educational organizations by the woman's auxiliary entitled "Planning Your Career as a Medical Associate."

5. The Second Rural Health Conference: This was held last September. More farm leaders served as panel discussants. The state health department participated freely. The sponsoring organizations list grew to forty-one. The conference was broken down into sixteen discussion groups, each treating a specific health problem such as community health councils, disease control, mental health, dental care, child guidance clinics, hospital construction, aid to medically indigent and health planning. The utilization of these small groups was found to be provocative of much freer discussion and expression of ideas. Thus, from just the spark of an idea two years ago, the annual State Rural Health Conference has grown to be a required institution fulfilling a real demand.

Other Results.—Action resulting from the first State Rural Health Conference was a determination developed by the people of one small rural community to build their own community health center in an endeavor to attract a new doctor to replace their recently retired 80 year old practitioner. This building will have offices for a physician and a dentist and a room for the county health nurse. It was completed entirely by local subscription of funds, without financial aid from any governmental agency or any medical organization. This community, on its own initiative, has undertaken to solve its own problem. This is as it should be.

How Great is the Rural Medical Need?—We could not answer this question, and decided to seek an honest answer, reached through investigation carried on in a scientific manner by an absolutely impartial observer. The Section on Sociology and Anthropology and the Social Research Service of the Michigan State College offered to cooperate. A research technic known as the "Symptoms Approach" was used. A carefully selected list of symptoms for which a doctor usually looks in taking a medical history are listed in nonmedical terms so that a person of nonmedical training, if carefully instructed, can obtain the desired information. Graduate students were employed to conduct interviews in one thousand households throughout the state. This part of the research has been completed. All findings are recorded on punch cards. When our study is complete, we will know how much difference there is between the need for medical services in the rural and the urban portions of our population. We will know what people like and what they dislike in their doctors. We will know what they think of their hospital attention. We will know where the need for medical attention is most urgent. A surprising percentage (about 70 per cent) have never heard of "socialized medicine." The survey is based on the assumption that the producers and the consumers of medical services can be most successful in their efforts to improve rural health if strictly scientific procedures are employed in determining the attitudes of the people and if the findings are publicized to both doctors and patients when the studies are completed. The study has cost over $12,000 thus far. We believe that this study when completed will prove of great scientific and sociologic value.

Information to Rural People.—During the past two years we have released 13,000 separate broadcasts over twenty-six different stations. There is no rural or urban area in the state which is not covered. These broadcasts are daily, five minutes long, and are devoted to scientific subjects of current interest. They are prepared and broadcast by a nationally known commentator in layman's words, and are checked for accuracy by doctors of medicine. We have spent $46,000 during the past two years in their preparation, but we have enjoyed the use of $240,000 worth of radio time, the balance being contributed in the public interest by the radio stations or commercial sponsors. Over 500,000 informational pamphlets have been distributed. A motion picture, "Lucky Junior," was prepared illustrating the advantages that the child of today enjoys over his parents, with emphasis on immunization. This picture cost $15,000, but it is being shown in four hundred commercial theaters.

Rheumatic Fever: Thirty rheumatic fever detection centers were organized, covering all sections of the state, to serve as diagnostic aids to referring physicians. A full time coordinator, a doctor of medicine, is in charge of this program. Over 4,000 patients have been referred to these centers by over five hundred doctors, and returned to the referring physician with consultation advice. The rheumatic fever budget is $55,000 this year.

Enrolment in Voluntary Prepayment Insurance.—Believing that voluntary prepayment insurance for hospital and medical costs constitutes the chief answer to the greatest problem in the medico-economic field for rural people, our Rural Health Committee requested opportunity for the rural people to enrol in our Blue Cross, Blue Shield insurance plans as individuals in communities, as well as in employed groups. Five hundred and eighty-three Farm Bureau groups and fifty-two Grange groups are now enrolled in Blue Cross, Blue Shield, in two-thirds of our counties. Total enrolment in Blue Cross has risen to 1,500,000 persons in the state. Blue Shield is not far behind, with over 1,300,000. The monthly expenditure in behalf of the subscribers by Blue Cross and Blue Shield is averaging $2,250,000, or $27,000,000 a year. The Blue Cross and Blue Shield are presently developing a statewide enrolment campaign during which any person in the entire state may secure prepayment insurance, thus obviating the chief objection to this type of insurance. One can visualize the time when the entire population of the United States, barring those on relief, may have voluntary prepayment insurance, covering the cost of hospitalization, surgery and obstetrics.

Summary.—In summarizing the activities of the Rural Health Committee in the one state about which I am able to speak, we have tried to meet and recognize the problems involved in the medical needs of rural people. We are aiming at their solution. We realize that we are far from our goal. To date we have instituted action in nine fields.

Such a program costs money, but we believe that medical societies and other organizations interested in the health of rural people should be willing to raise and spend funds—on their own initiative—for a cause which is obviously for the betterment of rural people.

When the rural people of America become sufficiently interested in their own problems to spend their own time, their own efforts and their own money to attempt to solve their own problems, without delegating that task to authority by remote control, we shall have more hope for the future.

Chairman Crockett: The next paper will be "Animal Diseases Affecting Human Beings," by Dr. H. B. Mulholland, of the Committee on Rural Health.

Animal Diseases Affecting Human Beings

Dr. H. B. Mulholland, Charlottesville, Va.: No attempt will be made to cover all the diseases occurring in animals which may be transmitted to man, nor will the field of diseases where animals may act as carriers or host be comprehensively covered. The most important conditions in both categories will be reviewed and measures outlined for their control, with emphasis on the necessity of close cooperation of physicians, veterinarians and farmers in decreasing and eradicating these various scourges.

Bovine tuberculosis will be reviewed as an example of the results obtained by cooperation between government, farmers and doctors. This type of the tubercle bacillus is of minor importance in causing tuberculosis in human beings in this country because of rigid control measures in cattle, whereas in European countries with less control a significant number of cases result from contact with the bovine type of organism.

Such diseases as equine encephalitis, rabies and tetanus constitute a group to which the rural population is constantly though infrequently exposed, and constant vigilance must be maintained in order that their spread be minimized.

Of interest is the type of influenza found in swine. Never described before the great 1918-1919 epidemic of influenza, the possibility of the human virus of influenza plus the influenza bacillus being carried over to swine is an intriguing theory.

In many rural areas, particularly those of the South, tularemia is of major importance in causing serious illness in human beings. While the wild rabbit is the principal vector, many other species have been known to carry the disease to human beings. Similarly, Rocky Mountain spotted fever may be a serious disease in many rural districts and, like tularemia, may be carried by many vectors other than the wood tick. Methods of control and treatment have advanced, and the discovery of new antibiotics seems of great import in their cure.

Ornithosis, an interesting disease of virus origin closely related to psittacosis, is found frequently in rural sections. The virus has its habitat in pigeons and barnyard fowl; a recent epidemic was found to originate in Long Island ducks. This disease may become of major importance to farmers. Fortunately, it is mild and responds to penicillin.

"Q" fever, first described in Australia, has broken out in this country, and is associated with the handling of cattle, being transmitted by ticks.

Brucellosis, more familiar to the farmer as undulant fever, caused by organisms causing contagious abortion in cattle, still remains one of the foremost problems in medicine today, causing untold suffering and economic loss both in cattle and swine and in human beings. The measures adopted for control of bovine tuberculosis have not proved satisfactory in lessening the incidence of this infection. Vaccination with type 19 is of value and isolation of infected swine helps. Unless the latest antibiotic, aureomycin, proves effective, the treatment of chronic human infection is discouraging.

Education of farm people in the fundamentals of transmission of these diseases in animals and man is paramount, and constant vigilance must be maintained, even though some of them are seemingly well under control, else they will break out afresh.

Liaison between the medical profession, farmers, veterinarians and government agencies must be continued in our attack on these and other diseases.

Chairman Crockett: The next paper will be "Environmental Hygiene," by Dr. Ernest L. Stebbins, professor of public health, Johns Hopkins University.

Environmental Hygiene

Dr. Ernest L. Stebbins, Baltimore: Healthful living depends on man's ability to accommodate himself to the many and varied factors in his environment. We are inclined to think primarily of physical environment as it relates to health, but it is becoming more and more evident that we must be concerned also with our social environment and its relationship to health. Health, as it was defined in the preamble to the constitution of the World Health Organization, is complete physical, mental and social well-being. This is a much broader definition than we are accustomed to and certainly our knowledge of the effect of environment on health is limited, primarily to our physical environment.

Man has struggled with his environment since the beginning of the human race and has found it possible to adjust himself to a wide variety of environments. In fact, there are few areas on the face of the earth where man cannot adjust himself to his environment sufficiently to live in a reasonably healthy state at least for temporary periods. Man has tended to settle in those areas in which environmental factors were most favorable to his healthy existence. This has not always resulted in the ultimate improvement of his condition. The concentration of population in the more desirable parts of the earth's surface may create new environmental hazards; in fact, the vast majority of environmental hazards in a civilized country are produced by man himself. This has necessitated setting up a program of environmental hygiene.

Housing.—One of civilized man's first interests is the provision for shelter against the elements. The type of shelter that he provides has a definite bearing on his health, even though it is extremely difficult to demonstrate a specific health hazard resulting from poor housing largely because of the association of other environmental hazards with poor housing. One of the greatest environmental hazards of poor housing is overcrowding. Another less frequently recognized hazard of poor housing is the frequency of accidents. Good housing should provide safeguards against these accidents.

Water and Sewage.—Most frequently transmitted by water are typhoid and diarrhea or dysentery. Prevention of the spread of these diseases by water requires either that the supply of water be amply protected against pollution by human wastes or that it be purified. In rural communities, individual water supplies cannot readily be purified by filtration or chlorination; therefore reliance must be placed on measures to prevent pollution of such supplies. In rural communities the majority of households are supplied with water from a well. The location of the well in relationship to the disposal of sewage or other human wastes is obviously of great importance. Not infrequently the planning for the location of wells and the disposal of human wastes requires technical knowledge and skill. The type of well and the type of sewage disposal that best fit a given location may require extensive study and knowledge. A properly organized local health department should be equipped to provide consultation and help to the home owner or builder and to provide assurance that the disposal of human wastes will be such that they will not endanger the home owner's own water supply or that of others. It is entirely possible to eliminate completely the environmental hazard of contaminated water, but, unfortunately, every year many residents of this country suffer from water-borne disease.

Food Supply.—Another essential factor in any environment is an adequate food supply, but food, also, may be a transmitter of disease. One of the most important foods and one which is particularly liable to transmit disease is milk. This may constitute an environmental hazard if the cows from which the milk is obtained are suffering from diseases that may be transmitted to man, or if the milk is so handled that it may be contaminated by human beings suffering from a disease transmissible through milk. The two diseases of cows most frequently transmitted to man are bovine tuberculosis and undulant fever. Both of these diseases have real economic significance to the farmer as well as representing a serious health hazard, but by the use of simple tests for the detection of these diseases and by the elimination of infected members of herds the rate of transmission to man has been greatly reduced and economic loss lessened. Milk from cows not known to be free from infection must be pasteurized in order to be safe or, if that is impracticable, boiled.

Not infrequently, certain infections of man may be transmitted to cows. Important among these are the streptococcic infections. This type of organism may be transmitted from the milker to the cow, producing disease in the cow that may not be apparent but which in turn may be transmitted to man through the milk. Constant vigilance on the part of the milker is necessary to detect such infections and avoid the possibility of transmission to man.

A serious but fortunately rare hazard in connection with food consumption is the disease known as botulism, a highly fatal disease contracted by eating food which has been contaminated with the organism and improperly canned. Prevention of botulism is largely a matter of education of housewives concerning the proper methods of home canning of foods. The organism is destroyed by proper heating, and safe methods of home canning have been devised.

Food may be contaminated with a variety of organisms which produce toxins or poisons if the food is kept for some time after cooking and is not properly refrigerated. Many of the common diarrheas result from this type of contamination of food. Prevention of these common diarrheas is accomplished primarily through the proper handling and refrigeration of foods not consumed promptly after cooking. It has been found to be a dangerous practice to leave unrefrigerated any foods that may have been handled subsequent to cooking.

A specific health hazard is involved in the eating of pork if not sufficiently cooked. Trichinosis is a food infestation transmitted to man by the eating of infested pork that has not been sufficiently cooked. It is not a highly fatal disease but produces a great deal of discomfort and disability. It can be readily prevented by thorough cooking of all pork.

Other Hazards.—There are other hazards in the environment of certain parts of the rural areas of the United States. One of the most interesting of these is Rocky Mountain spotted fever. It is known to have a rather wide distribution throughout the United States and is transmitted to human beings through the bite of a tick. The best means of avoiding this disease is to avoid tick-infested areas. A special vaccine has been developed which has been shown to be effective in preventing the disease.

Tularemia may be a hazard in the environment. Infection of man results from the handling of infected rabbits or other rodents or through the bite of a tick, flea or other insect which has been in contact with an infected animal. This disease may be avoided by keeping away from rabbits in infested areas or by careful handling of rabbits. Persons whose occupation requires that they handle rabbits that may be or may become infected should be protected by a vaccine.

One of the greatest hazards in the environment, particularly in the Southern states, is malaria. The prevention of malaria is such an extremely complex problem that it would be impossible to discuss it in this short period of time.

Our Nonphysical or Social Environment and Its Relation to Health.—It has been increasingly apparent that the sharp differentiation between physical illness and mental illness, which has so long been maintained, cannot be justified. The frequency of psychologic causes for disability often presumed to be physical has resulted in a new approach to medical problems, taking into consideration the psychologic and family background as well as the physical background of the individual patient. This has been called psychosomatic medicine. Moreover, it has been shown that many of the behavior problems of children, which all too frequently lead to definite mental disease, are preventable. There is growing evidence that the social environment, particularly the family environment, has a great influence on psychologic development. Our knowledge of this field is admittedly limited, but efforts are being made to recognize hazards in the social environment and to provide safeguards against these environmental hazards. Many health departments are now undertaking to develop safeguards against these hazards through the establishment of mental hygiene clinics for the diagnosis of the defects in the social environment and to provide simple means of preventing serious damage resulting from these social environmental hazards.

Mental hygiene has been defined as a technic which aids the individual in securing satisfactory mental and emotional adjustment to his environment. The evidences of hazards in the social environment may appear early—the so-called problem child is usually one with a behavior problem, one who has temper tantrums, does not get along well with other children or, in extreme cases, may show early signs of delinquency. Such a child may have a hazard in his social environment. Most frequently, this is not a problem of the child himself so much as it is a problem of his parents. There have been some most encouraging results where these problems were recognized early and through psychotherapy, particularly with parents, the cause of these difficulties has been removed. Not infrequently in the adolescent child more serious difficulties are encountered, leading to juvenile delinquency or mental disease. Careful study of such cases has led to the belief that a large proportion of those involved are subject to emotional or social environmental stresses with which they are unable to cope. Here again much of this is due to failure on the part of the parents to understand the child's problem. Often these problems of the social environment are also associated with some physical disability. There seems to be a great prospect for future accomplishment through the mental hygiene movement, eliminating many of the hazards of the social environment.

With few exceptions, in discussing the problems of our physical and social environment, the place of the health department in meeting these needs has been obvious. In meeting the needs of environmental hygiene, whether physical or social environment, the need for a well organized, functioning health department should be apparent. The extension of full time local health departments to that part of the nation not now served is imperative if we are to solve the problems of our environment.

Nutrition and the Soil

After a short recess Dr. Carl S. Mundy, vice chairman, introduced the next speaker, Mr. Glen W. Bunting, Manager of the Central Farmers Fertilizer Company, Chicago.

MR. G. W. BUNTING, Chicago: Comparing daily newspapers of fifty year ago with those of today reveals some interesting similarities; accidents, then and now, especially sudden disaster, are prime news. Fifty years ago the daily newspapers in Chicago gave no indication that food and health had any relationship—at least a casual checking of old papers does not reveal any public interest in the subject.

The actual problem of proper nutrition may not be materially different, but the ease of transportation has allowed many persons to make observations that stimulate their thinking on the subject. Driving through the northern counties in Florida, especially off the main highways, one is impressed by the sight of starving cattle walking in lush-appearing vegetation but lacking in the necessary minerals to give health. The rural people who produce most of their food from these infertile, sandy fields plainly indicate that malnutrition is not limited to Greece, China or India.

For purpose of contrast, let your mind travel into the semiarid West where vegetation is sparse but the cattle are in good flesh, with a healthy coat of hair and appear to reflect the optimum of proper nutritional diet. Likewise, the health of the rural people of that area reflects a better nutritional diet.

Dr. Abbott and associates found up to 85.2 per cent of rural school children (age 6 to 10) in Florida in 1939 were anemic, whereas a study by Wiehl and Kruse in 1941 found only 1.5 per cent anemic among 336 private school children in New York. It is apparent that proper proportions of iron, copper and cobalt are lacking in the daily diet of the children in rural areas of Florida.

A recent study by J. E. Steckel of Purdue reveals a widespread area in Northern Indiana where crops show definite starvation for manganese.

Cobalt, iodine, manganese and copper have been found necessary for control of the death losses of sheep in Northern Wisconsin. Is it not reasonable to assume that the health of rural people in the same area is affected by the same mineral deficiencies?

VICE CHAIRMAN MUNDY: Our next paper, "Health Education and Community Responsibility," is by Mr. Aubrey Gates, Associate Director of Cooperative Extension Work, College of Agriculture, University of Arkansas.

Health Education and Community Responsibility

MR. AUBREY D. GATES, Little Rock, Ark.: The object of the National Conference on Rural Health is to bring to rural America the kind of health service needed and desired in a manner that is in keeping with American ideals. The approach is necessarily through health education and community responsibility. Moreover, the approach is necessarily a program of action if any sort of solution is to be reached.

Health education and community responsibility are rather broad terms. There are two big educational jobs to be done in the field of health education. One is with the lay public. They must be made to realize what they can expect and what they can do both as individuals and as communities. We must take the lead, and everyone else must help. The other big job is with the medical profession. Each group must keep in a position to counsel and advise the other—but never to dominate and dictate.

An advisory committee was set up composed of representatives of the medical society, hospital association, University of Arkansas Medical School, state health department, the Arkansas Farm Bureau Federation and home demonstration clubs. We find that the whole problem of health education in a community is bringing together diverse interests in the whole undertaking; reaching an agreement, and developing a program along lines that will lead to ultimate solutions.

Adequate medical and hospital care will come as a result of study and discussion and of compromise. We have a great body of factual information, it is true. But health education is not an exact science and must be tempered by judgments and practical application.

Conferences on rural health have set the pattern for people to come together to discuss openly what they should do to provide their own needs and find ways of solving their own problems. If a satisfactory program for rural health facilities is not worked out by the people themselves—both the lay and the professional groups, it is a fairly safe assumption that one will be developed by an Act of Congress to be administered by the federal government. To me this is socialized medical care of the worst sort.

Our best argument against a legislatively provided medical service is the lack of information on what is needed by or acceptable to the people. Regardless of how well science and technology are developed, it is public understanding and continued practice that count. If medical service can be made available only by act of the national Congress, it is my opinion that we have made the first step toward completely controlled social and economic life and will have given up the right to take free action in this country.

Rural people know that something needs to be done for better health facilities. The medical profession surely knows that such a problem exists. The difficulty, it seems, is that we do not know where to take hold, or some of us are unwilling to do so.

Many advances are easy to overlook when we get into the heat of discussion of what we are going to do. But stop and think. The life span has been increased; twenty-five years ago it was only 35 years. Now it is 65. That did not just happen, and all of us know the reasons for it. The public's knowledge of sanitation and disease prevention, the skill and technical advancement of the members of the medical profession and many more things played a part. In the South nutrition, sanitation and disease prevention have been an important part of our extension education and farm organization programs.

For several years the Medical School of the University of Arkansas has been unable to locate a case of pronounced pellagra. Occasionally they find a case of subclinical disease for laboratory observation by the students. That is all. Disappearance of this disease is attributed to the education on nutrition that has been offered in recent years.

Almost everyone working in rural areas has done much on sanitation programs. Typhoid was greatly reduced even before immunization came into use, through safeguarding the water supply and screening against flies.

Much educational work has been done and real progress has been achieved on control of malaria. Recently in the Southern states whole counties have joined together to bring the public health service into homes with DDT spray equipment. The Arkansas Farm Bureau Federation and its affiliated county units have taken the leadership in sponsoring venereal disease clinics, with surprising cooperation and results. Both the state health department and the local physicians whole-heartedly cooperated in handling technical aspects of the clinics.

There have been outstanding successes with tuberculosis clinics, cancer clinics and well child clinics. These were the finest kinds of cooperation based on full understanding. That is the only way that they could have been successful. People have been made to understand fully their purposes, objectives and results in terms of personal and community welfare.

These are controversial questions: How will we meet the need of the "disappeared" rural doctor? How can we get one in his place? How is he to be paid? What kind of workshop can be made available to him? Why can't these questions be worked out like others—merely by bringing the discussion into the open and, through the people concerned, reaching an understanding of what is best to be done.

Much that could be done will not require a long or complicated educational program. For example: In one Southern state 26 per cent of the children born last year were without an attending physician. Yet in that state law does not require midwives to meet any standard. In the near future the state's legislature will probably pass a licensing law for midwives.

We need not stop at doctors and nurses. Laboratory technicians, sanitary engineers, and many other types of workers are needed. These should leave the rural community for training and return there for service. It is our job to show them the opportunity and the challenge. Communities have another responsibility: That of obtaining sufficient appropriations for adequate training facilities so that larger numbers can be enrolled and trained.

In Arkansas about 75 per cent of the hospitals are owned and operated by individual doctors or partnerships of two or more doctors. It is obvious that the young practitioner has not the financial resources to build and equip even a small plant. Some type of community action must be taken if this problem is to be met.

Developing an over-all hospital program in a state involves endless educational work and great community responsibility. Many of our doctors readily state that they do not want to own a hospital. They own them because they wanted to practice in the rural area but needed the facilities to carry on successfully. They built hospitals and bought the expensive equipment themselves. They said nothing to the public about this responsibility —neither did we. So, over the years rural people have looked on this as the proper and only way to have a hospital. They expected doctors to build hospitals, employ and pay for highly trained personnel, do the managing and all the practicing. All the public expected to do was utilize the service when needed. The whole thing now is too big for the individual doctor to handle along with his practice.

There seems to be a tendency in our section of the country for the general practitioner to give up his hospital and either join the staff of a nearby hospital or encourage the people to build or operate their own. This can be done with the assistance of the federal funds under Public Law 725. Before a state could participate in these federal funds it had to make a survey to show the need of additional hospitals and draw up a plan for a well integrated hospital system. A department of hospitals had to be created within the state government if none existed. These things have been done by all of the states, and all are eligible for federal funds. The principal purpose of the department of hospitals in most states is to supervise construction details and standards and enforce the hospital licensing laws.

The weakness of the program lies in the fact that the construction and operation of a complex institution is being turned over to an untrained and inexperienced public. This must be corrected. There is an urgent need for us to launch a full scale program of educating the community as to its responsibility, in properly incorporating this business institution, getting a board of trustees or governors free from political or personal bias, employing well trained management, avoiding large yearly deficits brought about by inferior management, and taking proper care of necessary operating deficits incurred by non-use. If costly mistakes are to be avoided in this or any other undertaking, we have a responsibility to see that we are working with all the facts we can obtain, in full faith and complete confidence.

Vice Chairman Mundy: Our last paper on the program, "The General Practitioner in Rural Practice," is by Dr. Ward Darley, Executive Dean, Health Sciences and Services, University of Colorado School of Medicine, Denver.

The General Practitioner in Rural Practice

Dr. Ward Darley, M.D., Denver: The National Conference on Rural Health is unique in that its participants represent both the consumers and the providers of medical service.

The increase in medical knowledge during the past twenty years has been phenomenal. Consequently, it should not be surprising that we are experiencing difficulty in translating this knowledge into effective action. The situation is complicated by the fact that the consumer group is well aware of the increased potentiality of medical care and naturally is actively interested in seeing that the best possible care is made more readily available. Many obstacles present themselves as far as the realization of this desire is concerned. The greatest of these are to be found in the uneven distribution of hospitals and diagnostic facilities and in the uneven distribution and actual shortage of physicians and other health service personnel. Further, without attempting to go into controversial details, it must be recognized that changes in our industrial, economic, social and political world are pressing on us from all sides, increasing the tempo of our lives, adding to the confusion of our environment and consequently making clear thinking and sound judgment difficult. All this is having a profound effect on all thinking and activity which is concerned either directly or indirectly with the maintenance of health and management of illness. The result is that there is a wide gap between actual medical knowledge and the type of medical care rendered.

It should be obvious that if progress is being made, a gap between what we know and what we do is bound to exist. The efforts which are being made to narrow this gap are simultaneously creating problems which are adding to our basic difficulties. It is inevitable that, as knowledge accumulates in any field, specialism and segmentation take place. Specialism has made it possible for the individual physician to become particularly adept in some one segment of medical practice and thus to pool his particular ability along with the particular abilities of other physicians to the end that a more effective and better balanced medical care may be made available to the consumer.

While it is true that the acquisition of scientific knowledge and the consequent development of specialism and the need for special equipment and facilities have brought us definite benefits, specialism, segmentation and their consequences are doing much to set aside and dilute the patient-physician relationship—the most important foundation stone of a satisfying type of medical care. In fact, I do not believe that medical care, no matter how superior it may be from the scientific point of view, can be truly effective unless the patient-physician relationship permits the physician to make the maximum use of his own personality as an agent of comfort and therapy. A system of medical care that passes the patient from specialist to specialist, that depends in a large measure on the services of nurses, interns, residents and assistants, that involves technicians and their paraphernalia and that takes the patient away from his home and frequently his community, of necessity becomes impersonal.

Specialism and "hospitalism" are not the only factors that are operating to impersonalize medical service. Good roads and comfortable and rapid means of transportation have influenced doctors to concentrate in localities far removed from many of their patients; the patient therefore must more and more come to the doctor instead of the doctor's going to the patient. This, while doing much to increase the efficiency of our doctors as far as the number of patients that they can see in a day is concerned, is wrecking havoc with the patient-physician relationship because of the necessary cut in time per patient.

The health services in schools, universities, business and industry offer a very impersonal type of medical care. Most health service for the indigent is impersonal in its approach. Finally, I submit that any type of medical care insurance, whether it be voluntary or otherwise, tends to be impersonal because the usual two way patient-physician responsibility is diluted by the entrance of a third party—the insuring agency.

Chancellor Robert M. Hutchins of Chicago University in a recent statement strikes at the core of the situation by saying: "Specialization is essential to the increase of our knowledge. . . . But specialization does not facilitate the comprehension of knowledge: it is not likely to show us the interrelations among facts and ideas in various specialized fields."

Dr. Wingate Johnson, speaking from this platform one year ago, expressed this same idea in more practical terms when he said: "The same factors creating the need for specialists are creating the need for men trained to guide patients through the maze of modern medical care."

If a general physician is to assume the role of a "general manager" in our system of medical care, what is the ideal way in which he might function? Briefly, I feel that he should be in a position to function as a health counselor or coordinator from birth to death. In order to function effectively in this manner he must also be in a position to render preventive, diagnostic and therapeutic services consistent with the average person's average needs.

Medical care of tomorrow will undoubtedly place great stress on the personal as well as the community aspects of preventive medicine. The practice of personal preventive medicine will have comprehensive implications. In addition to the usual immunizations and efforts to instil the commonly accepted principles of personal hygiene, a working understanding of mental hygiene and clinical psychiatry will be essential. I believe that the greatest single challenge in the field of preventive medicine today is in the area of emotional and personality-determined illness. The exertion of intelligent influence on the individual, particularly during the early years of his life, and on the family of which he is a part, can do much to prevent the full blown neurotic conditions which constitute or complicate about 50 per cent of the average physician's practice. The preventive idea must embrace the recognition and adequate treatment of the early neurosis. It is unreasonable to expect psychiatric specialists to care for all of the psychiatric needs of our people. Ideally, the family physician is the one who first will see the average patient needing psychiatric guidance. By virtue of his knowledge of the patient and his environment, he is the one in the best position to render the most effective service. This general physician, however, must be well enough trained to recognize his limitations and thus know when the services of the psychiatric specialist are needed.

Almost all of these remarks can be applied in principle to the relationship of the general physician to the fields of pediatrics and internal medicine. Maximum effectiveness in the early diagnosis of medical and surgical conditions will be essential. This is a large order, particularly if a patient with suspected disease is to be kept under observation without being subjected to unwarranted anxiety and expense.

What I am saying is that the general physician should be the one to continue at the helm during and after any episode of illness so that he can do his utmost to prevent complications in the home and to prevent relapse, sequel, chronicity or disability in the patient. If chronicity or disability for the patient are inevitable, he should be the one to help the patient and the family to make the most of any remaining assets, develop others and steer the patient to and through a program of rehabilitation.

With the increase in the average life span of our citizens, the medical profession will be called on more and more to cope with the problems of the aged. Here early diagnosis, particularly of malignant or degenerative disease, will deserve diligent consideration. The medical care of the aged will always be complicated by conditions requiring the attention of the physician who has a working knowledge of both psychiatry and medicine. Obviously, the family doctor should be qualified to deal with these problems.

If general physicians are to cope with the preventive, diagnostic and therapeutic aspects of psychiatry, pediatrics, internal medicine and possibly surgery and obstetrics, and at the same time keep themselves in a position so that they can keep their services adjusted to the needs of their individual patients and communities, it should be obvious that their period of training must be just as long, just as expensive and just as carefully planned as that for any of the specialties.

There is much evidence that our general practitioners are already making an effort to rise to the occasion. Their demands for postgraduate opportunities are almost exceeding our ability to supply and their philosophy is rapidly adjusting itself to a broad, positive point of view. I believe that the general practitioner of today can most easily adjust himself to both the needs of today and of the immediate future. In line with this, my contact with general practitioners leads me to feel that they are making an honest effort to recognize their limitations and that their use of specialists is becoming very intelligent and reasonable.

It must be recognized that today many obstacles exist which are detrimental to the effectiveness, sense of security and self respect of our general practitioners. Many of our physicians, some specialists, some general practitioners, feel that the general practitioner is outdated and in time will disappear. Unfortunately, many of our citizens seem to hold the same point of view. I believe that searching thought about the background of American medicine and the things that are essential to a satisfying type of medical care will discourage any one from holding to such convictions. Careful consideration in the right quarters should do away with hospital staff discrimination against the general practitioner. By the same token, such units in our society as the armed forces, Veterans Administration, civil service, insurance companies, industry and medical schools, should cease to use board certification as the chief basis for the grading of its physicians and thereby automatically freezing the relatively lower status of the general practitioner, no matter how capable or effective he may be.

I feel that most of what I have been saying can be taken as applicable to almost any type of community in our country. I believe that a general physician should be the backbone of urban as well as rural practice.

In conclusion, I should like to reiterate: I believe that if the need and desirability of individualized physician-patient and physician-community adjustment is kept in mind, a general physician is the logical one to coordinate our plan of medical care. Further, I believe that a general physician's services should play an important part in the medical services offered to any type of community. If we compare the present relative needs of urban and rural communities, I believe that both the qualitative and quantitative needs of the latter are the greater. And finally, I believe that given a reasonable period of time—time for the construction of facilities and time for the education of personnel—the health needs of our rural communities will be worked out in a substantial and effective manner.

Saturday, February 5

Chairman Crockett: The meeting this morning is for the purpose of receiving the reports of the panel sessions of yesterday afternoon. The policy of these conferences has been that no vote is taken. We do not go on record by a vote of any sort as to the opinions expressed by the panels. The panels are independent agencies who have heard the testimony of all of you who cared to contribute, and in turn have gotten together and formulated their conclusions as to the sentiment expressed. We adopt the general attitude that we confer here and report largely those things which fall within the areas of agreement rather than to spend our time on debatable things which are probably not yet ready to be settled. If we can make a little progress once a year in coming here, gaining better knowledge of each other and of each other's intentions, we are approaching a common working solution to many of our problems.

Section chairmen will be asked in their rotation to come forward and present the findings of their panels, and then there will be a short period for additional remarks but those remarks do not have to be answered.

Committee on Cooperative Health Programs for Rural Areas

Mr. Chester Starr, Chairman: Our section divided the discussion into two parts: The local health council and the local health unit are so closely associated that they were discussed together; however, we had to make a definition because apparently a number in the conference were somewhat confused as to the difference between the two. A health council is an unofficial voluntary body of a number of persons who come together for the purpose of discussing, surveying and making plans for the improvement of health in the area. The local county unit or department is an official body, often performing a part of the state health department's duties in the state; it is officially charged with certain responsibilities by the state.

From the observations, it would appear that the majority of the people attending the conference thought that the membership in the health council should be voluntary, possibly made up of individuals rather than simply on an organizational basis. It should have something to do. If a health council does not have something to do or, in other words is not built to delve into problems and plan the solution of problems, it soon dies.

This section recommends that the National Conference on Rural Health go on record as urging that every local area establish a voluntary over-all coordinated health agency such as a health council or health committee. It further recommends the complete coverage of the nation with full time local health units in the belief that it is fundamental to the effective functioning of all health programs. This point of view has been set forth by other conferences, notably the House of Delegates of the American Medical Association at its intermin session in St. Louis, the Section on Local Health Units of the National Health Assembly and the National Advisory Committee on Health Units of the National Health Council. One of the primary objectives of a health council may well be the attainment of local health units where they do not exist and the strengthening of existing ones.

This section is in agreement with the present efforts of state and territorial health officers, the National Congress of Parents and Teachers and many other national organizations in supporting, in principle, legislation that is designed to attain the objectives of full time local health units coverage for the nation.

Cooperative Hospitals.—All hospitals other than proprietary hospitals are fundamentally cooperative in character in that they represent the coordinated efforts, both in construction and operation, of the government, health professions, private philanthropy and consumer interests. Regarding this as a reasonable concept of a cooperative hospital, we believe, will lead to less heated discussions and more constructive thinking and effort.

This section recommends that Congress be requested to extend the time of the operation of the Hill-Burton federal aid to ten years and to increase the appropriation from $75,000,000 each year to $150,000,000.

This group further holds that to build hospitals to supply all the nation's people with adequate medical facilities and to eliminate existing shortages, government grants-in-aid are necessary. Teamwork is required between rural and urban people, city, county and federal governments and the health professions.

DISCUSSION

Mrs. Dora Barney, Oklahoma City, Okla.: I should like clarification on the discussion on the cooperative hospitals. The impression that I got this morning was that perhaps everyone was against cooperative hospitals. I think that the difficulty was that many in the group were confused and associated cooperative hospitals with national health insurance and, putting those two together, were against the cooperative hospitals as well as national health insurance.

Mr. Eugene Butler, Dallas, Texas: We have about a dozen cooperative hospitals in Texas, and I believe that they are making a real contribution to the improvement of the rural health problem, and it seems to me that this body is making a serious mistake when it fails to endorse a program of this sort. Local people are getting together to solve their own health problem. It is about the only possible way that the problem can be solved and, personally, I am much distressed that this group has taken an attitude that there is any connection whatsoever between cooperative hospitals and socialized medicine. I am thoroughly convinced that the cooperative hospital is one step that will prevent what you doctors are pleased to call socialized medicine. It is one way that we can avoid socialized medicine.

Dr. John A. Ferrell, Raleigh, N. C.: In the discussion yesterday there was some difference of opinion as to the definition and exact meaning of the so-called cooperative hospital. The Hill-Burton Law makes provision for assistance to publicly owned hospitals and to nonprofit hospitals. If the so-called coordinated hospitals are nonprofit, they would not be excluded. Would it not be in the interest of clearness to indicate, instead of the term cooperative hospital, publicly owned and non-profit, hospitals, as stipulated in the Hill-Burton Law, and for which, in most states, state and federal aid are available?

Dr. Dean A. Clark, New York: The issue that was discussed in yesterday afternoon's session has not been made entirely clear. The controversy arose over the fact that in a number of places where cooperative hospitals have been attempted physicians who desire to associate themselves with such hospitals have found that they have been frowned on by the medical societies. It was the wish of many of us at the session that the American Medical Association would use its good offices to assist and encourage its state and local constituent societies to accept the cooperative hospital idea and not to discriminate against physicians who chose to participate in such hospitals.

Mr. C. C. Bair, Columbus, Ohio: I represent the Ohio Farm Bureau. The leader of our conference yesterday left the impression that a cooperative hospital, that any hospital could be described as a cooperative hospital because, in almost every case, there is a working together, a joining of government funds, and philanthropic donations and private working funds. Those of us who are in the cooperative would like to challenge that definition of a cooperative. A cooperative, basically, is the application of true democracy to an economic enterprise, which a hospital basically is. You have to have capital and you have to have a board of directors. You have to have management, and the determining factor to us in the cooperative movement is who basically is supplying the capital and, more than that, who governs it. In a true cooperative the people of the community, the consumers, each have one vote and have the right of choosing the management and choosing the staff.

Mr. Ray Miller, California: Mr. Chairman, may I ask you a question? I am a walnut grower from California. What is the definition we are discussing? Is cooperative mentioned specifically in your report or not?

Mr. Starr: We did not wish to discriminate in defining hospitals, but we did feel that this should be pointed out, and this is the definition, or rather it is the report submitted.

"All hospitals other than proprietary hospitals are fundamentally cooperative in character in that they represent the coordinated efforts, both in construction and operation, of the government, health professions, private philanthropy and consumer interests."

Mr. Miller: I think that your definition, wherever you got it, is about 75 per cent wrong. Government sponsorship, government control, private philanthropy and so on, all have their place, but they are not a part of what we commonly speak of as cooperatives. A cooperative is not different from the Associated Press and most of us know it. The Associated Press is the greatest cooperative in the world. Cooperatives are definitely a part of the American private enterprise system, and it is one of those things that can keep local control in local communities. It is the direct antithesis of statism.

Chairman Crockett: Each panel chairman will have two minutes to make any explanatory remarks that he wishes.

Mr. Starr: We did not think that we would encounter the rather strict definition that some sitting here are thinking when we say the word "cooperative." When we drafted that particular statement, we had in mind setting forth that except for proprietary hospitals and such hospitals as are operated purely by the government, no one benefits from the operation of these hospitals except the consumers. Hospitals do not make money. Most of them run a deficit, and that deficit has to be met by either private subscriptions once or twice a year, by campaigns or, if they are state or county or municipal hospitals, by public taxation. We felt that there was criticism of hospitals such as was mentioned by the gentleman from Texas and that the criticism was coming from people who had actually thought the thing through, that a hospital is for the benefit of the consumer, and other than proprietary hospitals, no one receives any income on any investment that might be made or contributed. It appears that we ran into difficulty possibly because of the jealousy of some groups in defining the word "cooperative." We hoped that our definition would clear the fog around the word and get more persons thinking of the true characteristics of all hospitals other than those operated for proprietary reasons.

Committee on Environmental Hazards

Dr. D. G. Miller, Chairman: Our conference was divided in three parts, and we will give our report in that way.

One of the contributions of the veterinary profession to public health is the control of diseases of animals communicable to man. At present, there are some seventy to eighty known diseases of this type. Additions to this list are being made constantly. Just recently, a member of the staff of Ohio University definitely established that Newcastle's disease in poultry infects human beings.

The veterinary profession takes great pride in the work of reducing the incidence of tuberculosis to less than 0.5 per cent in the cattle population in this country. This means that we have practically eliminated the incidence of tuberculosis of bovine origin in the population in America. However, we must not become too complacent; so long as a vestige of the disease exists, there is a distinct possibility of its again becoming a public health menace. The disease in cattle is on the increase. We cannot, therefore, relax in our program of regular retesting to keep the disease under control.

Brucellosis is perhaps of the greatest importance from the standpoint of public health. This is a disease which affects dairy cattle, swine and goats. The two forms of the disease which are most important from the standpoint of public health are those which affect swine and dairy cattle. The brucellosis of goats has not assumed any great importance in this country, and there have been only a few outbreaks of the disease from goats in the southern part of the United States. Farm people and those drinking unpasteurized milk are the ones most commonly exposed to the disease from cattle; while the swine disease is a result of packing house workers and farm folks handling diseased hogs.

The program of reducing the public health hazard is related to the control of disease in animals. This is directly dependent first of all on a sound educational program to inform the public of the dangers attending this disease in order to stimulate precautions by all the people concerned and the elimination of the disease from the farm herds and flocks. Many with ordinances require pasteurization of milk but allow unpasteurized milk in the use of butter, cheese and ice cream. The program has been held up to some extent as a result of inadequate federal services, which we feel will be corrected in the near future. Regular testing and the elimination of infected animals from all flocks and herds will be an important step in the control of this public health hazard, along with milk ordinances and pasteurization of all milk or milk products consumed by human beings. Perhaps even that fed to farm animals should be pasteurized.

Rabies results in so much anxiety and cost for the administration of prophylactic treatment to the large numbers of persons exposed that it is a serious public health problem. England and the Scandinavian countries have eliminated rabies from their boundaries and have maintained them rabies-free through a program of proper quarantining of dogs. In this country, the work has been hampered by a few misguided persons posing as dog lovers who refuse to have any restrictions placed on the dog. At present, we have all the means at our disposal for controlling this disease through proper quarantining and the vaccination of dogs and could greatly reduce and possibly eliminate the disease from this country. Since it has been established in wild life, a new program aimed at control of this disease should be placed in the hands of the public health groups, Bureau of Animals and the Wild Life Service, cooperating in a program of total eradication.

The second part of our discussion was on farm accidents. There are annually 18,000 accidental deaths among the farm population. Over 25 per cent of the accidental deaths in the United States occur among agricultural workers. The death rate among agricultural workers is exceeded only by the mining and transportation industries; 7,000 of these are caused by traffic accidents, and this number is on the increase. Six thousand, five hundred are home accidents, largely due to falls. Four thousand, five hundred are actually due to the farm work and are accompanied by 225,000 serious injuries each year. A large number of farm accidents have been shown to be caused by a removal of guards and safety devices or a disregard of elemental safety.

Our conference suggests: (1) that this problem may be in part solved by an organization of all the people interested in reducing this number of injuries and deaths to coordinate a farm accident program; (2) that there is a great need for research into the details and patterns of farm accidents so that exact information may be obtained; (3) that we must employ more safety technics, and (4) that we must embark on a comprehensive educational plan including schools, 4-H, the Farm Bureau and the Grange and all similar groups.

The third discussion involved environmental sanitation. In rural United States, statistics show that we have done well with environmental disease control since 1900. Since then, disease rates have levelled off and do not show as strong a downward trend as is desired by public health authorities, physicians and farm leaders.

It is the advice of this group that more emphasis should be placed on research in rural health sanitation problems; development of adequate water supplies and satisfactory means of chlorinating the individual well supply, and coordinating the planning of small villages so that adequate sanitary facilities will be provided. The four fundamental requirements for health and welfare of the people may be itemized as (1) water supply, (2) disposal of excreta, (3) food and (4) housing. It is emphasized that none of these may be obtained if disposal of excreta is inadequate. Chemical measures offer a temporary and poorly accepted substitute for environmental sanitation. If you do not believe that, try to persuade the teacher to stir some sodium hypochlorite solution or some other form of chlorination in her bucket of well water and see how far you get.

Decline in death rates of certain diarrheal diseases is due to better therapy, resulting in a shorter duration of the diseases and decrease in spread of infective fecal material, as well as the improved therapeutic outcome. This we do not feel to be due to the use of DDT, which Mr. Urey would like to make us believe.

DISCUSSION

Dr. Stuart A. Adler, Albuquerque, N. M.: I think that we have passed the stage where we take better care of farm animals than we do of our children. We ought to move that up to the point where we are saying that farm people take as good care of their children as they do of their stock. The next time that we meet we may be able to surpass it.

Dr. C. H. Lerrigo, Topeka, Kan.: Senator Capper is keenly interested in health matters. The point that I wish to make is that you do not advertise yourselves sufficiently through contribution of articles to your home papers and to your farm papers especially. No doubt this group numbers readers of *Capper's Farmer*, readers of the *Kansas Farmer*, readers of the *Missouri Ruralist*, readers of *Ohio Farmer*, of *Michigan Farmer*, of *Pennsylvania Farmer*. Every one of these papers would welcome this material that you are discussing this morning. Those are things that I think will advance your work tremendously.

Chairman Crockett: I want to thank the doctor for calling attention to the thing that has been often discussed in our committee meetings. It is a hope that sometime we may do our part, at least, by contributing a health column or note or contribution sponsored by this health committee to various farm journals. However, those things are difficult to work up and have acceptable; it is a field of journalism with which we are not too familiar.

Committee on Health Education—Individual and Community Responsibility

Dr. Roger Corbett, Chairman: One of the most important things that I can do is to report on the discussion method that Mr. Miller of Michigan followed. The whole group was divided into ten small groups. We had about one hundred persons, and so we had about ten persons in each of these groups. Each of these groups were to decide on the question which they wished the whole group to discuss. They were also to choose a spokesman. Then Mr. Miller brought them back into the group as a whole and for about an hour, these questions were presented and discussed. Mr. Miller then directed us back into the smaller groups with the suggestion that we bring out something on how to get a good job done in this field, and to choose a representative as a member of a panel for the whole group.

These are the ten questions that the ten groups presented to the whole section: 1. How to make rural communities health conscious. Who will take the leadership? How is action to be obtained? 2. What is the need for research and study on health and medical needs? How are the health problems determined? 3. What should we emphasize in a health program? What are some of the common objectives of a health program? 4. What are effective ways of solving health problems? Once that we know the problem, how do we meet it? 5. How do we interest members of the community not members of organizations? What percentage of the population belongs to some organization? 6. How can we effectively reach the underprivileged group of our community? 7. Is compulsory vaccination and immunization of all a good thing? Can one legislate good health in a community? 8. How can we coordinate the interested groups in the community? Who will take the responsibility? Who will assume the leadership? How is the domination of a single group prevented? 9. How can we make health a male as well as a female responsibility? In one state, it was reported that the men felt that health was the responsibility of women alone. 10. How can we develop concern? How can we interest an organization? How can we arouse individual interest in health problems?

Then we had a panel discussion. We have summarized all this discussion under two headings: motivation, and mobilization and organization.

We came to the conclusion that motivation was one of the most important things. It was suggested that the "pocketbook" is always a motive. Good health influences income among farmers.

A specific desire is that of boys and girls to excel in sports. Good health and posture are essential to success in sports.

As a part of this first step, get the various organizations acquainted. Obtain decisions as to what are the main problems. When you have the problems clearly set out develop a systematic plan for publicity based on facts.

One thing that interests all parents is the number of school days that are lost by children because of sickness. Use success stories—what other counties have done that has been successful means something. Enlist the cooperation of the schools. Make use of health problems as illustrations in teaching. Take advantage of opportunities presented by crises, such as floods and epidemics.

The last main heading is mobilization and organization. How can we get organizations and individuals who do not belong to organizations together? Interviews with persons scattered all over the area appear to be the only means. Maintain a strong line of contact between the health council if that is what you are setting up, your health committee, and these community organizations.

The members of the health council or the committee should be made up of actual representatives of the community organizations, not chosen from the top but chosen by the organizations themselves. Participation is a key means of developing organization and maintaining interest.

Getting together is a start; working together is progress; staying together is success.

DISCUSSION

Dr. D. G. Miller, Morgantown, Ky.: The thing that I should like to suggest on the enlisting of the cooperation of schools in health education is the heart of the student's health grade. It depends on: (1) whether he had the examination required by the state department of education; (2) whether or not he attempted to correct the defects found in that examination, and (3) whether or not he had all of the immunizations that were offered either by the county health department or by individual physicians.

Mr. D. E. Lindstrom, Urbana, Ill.: There seems to be a conflict in thinking between group number one and this group in the organization of a county health council. The first group implies that it should be made up of individuals primarily rather than by organization representation. This group indicates that one should maintain strong and persistent contacts with the organizations of which the health council is made up. I should like to take a middle ground in that there is a place both for organizational representation and strong individuals on this health council, and therefore avoid that kind of conflict.

Committee on The General Practitioner in Rural Practice

Dr. Franklin Murphy, Chairman: Our panel did not organize itself in a streamlined fashion as the previous one did.

The panel represented all phases of medical activity including the producer, the purveyor and the consumer of medical service. The bulk of the three hour session was devoted to participation by the members of the audience.

Certain areas of agreement were rather clearly reached.

1. Full agreement was reached that there is a dearth of physicians in rural areas and that a real problem exists.

2. There was apparently universal agreement that this unfortunate situation was the responsibility of the medical profession and the rural citizenry. The resolution of the problem depends on joint interest and action on the part of both the physician and rural citizens. Health is not just the province of the physician, but in fact depends on unanimity of purpose by both the physician and the consumer; i. e., the community.

3. It seemed clear that the general practitioner or family physician is recognized as the crucial person in the provision of an adequate and effective rural health program. The responsibility of schools of medicine to redignify the family physician and to put him in his proper position as the crux of our over-all health problem was discussed with full agreement.

4. Wherever efforts have been made to provide adequate postgraduate training for the general practitioner, increasing numbers of young men have evidenced their interests in this type of practice. If we provide at the undergraduate level as well as at the postgraduate level opportunities for continuing professional improvement, more and more men and women will be directed into the channel of family practice.

5. The general public is somewhat confused about the apparent limitation of the number of persons who can be trained to practice medicine. It has been suggested that this is a self imposition of artificial standards on the part of the profession to keep the numbers of practicing physicians down to the economic betterment of the medical profession. It was pointed out that the standards of medical education which limit the numbers of persons who can study medicine are established for the protection of the people rather than the physicians and that, in fact, today all existing medical schools are operating at full capacity and that any increase in the number of medical graduates will come only by the provision of more adequate training facilities with associated increased operating budgets. There was complete unanimity that whenever and wherever increased production is demanded, it be accomplished with the maintenance of existing standards of medical education.

6. Essential services are in many instances provided by the facilities of a hospital. Outpatient operations of hospitals may not have been explored as widely as possible. Postgraduate or continuing medical education is in many instances most easily accomplished in and around the hospital. The point was made that the professional activities associated with the hospital call for constructive participation by the physician.

7. Wherever possible, cooperative efforts on the part of two or more physicians are desirable. Solo practice puts too heavy professional as well as social limitations on the individual. Practice of medicine in rural areas on a regional basis with helpful expert consultation appears to be increasing throughout the country. Its success depends on strict understanding on the part of the patient, the family physician and the specialist that there is a normal chain of medical service and that in all instances the patient will seek advice from the family physician first and that the latter will continue to maintain contact with his patient throughout the period of consultation if such is needed. The satisfying medical experience that such a relationship provides is immediately broken down if the family physician is by-passed, either by the patient on the one hand, or by the specialist-consultant on the other.

8. In various parts of our country productive and fruitful efforts are being made by the medical schools, the medical profession and the patients as represented by various lay groups. Members of the medical profession must intensify their efforts in the field of lay understanding of the problems of medical education and practice. The laymen present at our meeting seemed to feel that definite progress is being made in the resolution of these problems. The democratic way of mutual citizen-cooperation will continue to solve these problems without the application of all-inclusive and artificial formulas.

DISCUSSION

Dr. Roy Fouts, Omaha, Neb.: Having spent more than ten years in general practice, and all of that time in a small community or small town, and having been close to general practice or rural medicine, I have been in constant touch with the problems of the rural community and of the general practitioner or the country doctor. The problem of rural practice, or the need in rural medicine, is not going to be answered or does not lie in getting more physicians. I have always contended that we have enough doctors providing we had a proper distribution of those doctors; and it has been shown by a rather recent survey by Dr. Dickenson with which you are all familiar, I am sure, that we have more doctors at the present time than we had in years gone by. It was mentioned by the panel chairman that the responsibility was first of the doctor and then the community; later he did touch on the responsibility of our medical institutions and colleges. I think that their responsibility is just as great. Some medical schools are starting on a program requiring at the end of the sophomore year, or junior year, that two or three months be spent with a general practitioner as a preceptorship in a rural community. Many of the men will find out things about rural practice and about the country that they never knew before. They will find things that they will like. They will find opportunities. A great many of them, through formal association with the older man, will want to return. The standard of medical practice among the general or rural physicians is decidedly higher than it is among the general physicians in our cities. I believe that our medical schools have an obligation to teach and train and instil in their students the idea that there are opportunities in general practice or rural practice. Providing this preceptorship following sophomore or junior years will lead more men into rural practice.

The doctor who graduates from the medical school and immediately starts his internship and his residency with the idea of being a certified specialist without any general practice has lost a lot. He never becomes a real rounded-out doctor and does not become even a good specialist in many instances.

Chairman Crockett: Dr. Fouts is Vice-President of the American Medical Association. He speaks with authority.

Dr. Walter E. Vest, Huntington, W. Va.: In West Virginia we are hoping within the next few months to launch a program whereby interns and residents may go out into the rural communities for one or two months as an aid to physicians and still get credit for that service. The Attorney General in the state has recently ruled that the Public Health Council can do that. The Public Health Council with the aid of the Council of State Medical Associations and the hospitals of the state expect to try to put it into effect. We hope that will do something in stimulating men to find out just what is in rural practice in West Virginia and turn more and more in that direction. West Virginia is largely a mining state, and we are putting on this plan to relieve the men in the mine positions.

Dr. J. L. Caughey, Cleveland, Ohio: I should like to take up the challenge of one of the preceding speakers who put considerable responsibility in the hands of the deans of the medical schools in respect to the distribution of the graduates of those schools. I believe that idea erroneous. Distribution of physicians is determined largely without reference to anything that the deans may do or say while the students are in school. We cannot even tell them where to go for their internship, and what happens in their internship has a great deal to do with what they will do after they have finished their first year or two of graduate training. It seems to me that our students will not go into rural areas to practice medicine if they believe that the only thing that they have to look forward to is ten years of drudgery before they can go to a bigger city and be specialists. If they are going to go into the rural areas to practice medicine, it is going to be because of their interest in people, because of their desire for the close, continuing relationship of the family physician with his patients. We can try to instil that interest. In the selection of persons for medical school, we may find persons more emotionally fit for that line. But they will not go out into small communities to practice unless they find working conditions which they consider suitable. They will not go unless their wives are satisfied to go with them and find in the community something in the way of educational opportunity and social opportunity which will be satisfying. The medical schools do have a great responsibility in developing in the students the interest in the patient which is a necessary ingredient in rural medicine, but distribution depends on economic and social factors which are far beyond the control of the medical schools. The solo practice of medicine in rural areas is a strong deterrent to our students in seeking such a career. They know that within two or three years they will be working sixteen hours a day seven days a week, and none of our graduates seem to want to do that any more. Maybe they used to, twenty-five years ago, but they don't now. Some kind of associated practice, is absolutely necessary if our modern graduates are to be persuaded to go into rural practice.

Dr. W. L. Pressly, Due West, S. C.: This subject has been close to my heart over a period of thirty-two or thirty-three years as a family doctor in a small area, and I feel hopeful of the situation. The problem can be solved by the medical profession and its allied associates. A doctor should not attempt to practice alone. He separates himself from his family to which he has a responsibility and from the responsibility of his church and his school. If Dr. "A" likes pediatrics, for example, allow him to look after the children. I have through the years had associates some of whom after a few years thought they would like to get into a specialty, and many of them have. The medical profession must never lose sight of the fact that we have a direct responsibility to the people, and we must rededicate, if a rededication is necessary. I think we must never lose sight of this direct responsibility for the health and happiness of our people.

DR. W. E. BARSTOW, St. Louis, Mich.: There is one point that I think would be of interest and perhaps be of benefit to our lay members of this group, and that is the question of night calls. We hear throughout the country the complaint that our younger men will not get up and make night calls. In my early days of practice, the question of night calls was a bugbear. We were called out night and day and we had that to contend with all the time. In our locality, we have educated the population to the effect that a doctor does need some time to sleep and some time with his family. Most of the people, if they stop to think about that, will confine themselves to necessary night calls and emergencies. Now we do not have so much trouble. It is more a matter of thoughtlessness than it is of selfishness with the people—they think they can call a doctor when they like and they used to do it. That used to be the sentiment, but it is changing now, since they realize that their men are overworked. I think with a little work from our lay members among their localities that practice will be largely eliminated and, when it is, the younger men are going to be more willing to go into the country.

CHAIRMAN CROCKETT: Often when night calls are made the physician finds that it is someone that he never heard of before. It leads to the suggestion that if our lay people would urge on their groups that every family, while well, should select some doctor and advise him that they wish to be included in his group of families, so that he may look them over and know what their health assets and liabilities are when he is not hurried; then when they call him in the middle of the night he knows that he is dealing with one of his families for whom he has accepted responsibility. It would help to simplify the matter a great deal.

REV. V. A. EDWARDS, Nashville, Tenn.: I represent the rural ministry. They tell me that misery likes company, and when I hear the doctors and the discussions with reference to a reluctance on the part of the doctors and the responsibilities of the medical schools and that sort of thing, it seems to me that I am in a similar discussion where the rural ministers are also reluctant to serve in the country. A study is now being made of the number of resident ministers in the National Baptist Convention. To date that number is 10 per cent of the churches in the denominations being served by resident ministers. We are making the same plea for ministers to serve in rural areas. The attitude of wives about going to these areas is equally important in the ministry.

DR. MURPHY: We doctors are ridiculed because we talk about the human aspect of medical practice, the doctor-patient relationship. It ought to be perfectly clear that when we talk about the doctor in the community and his concern with his patient and the fact that there must be community cooperation and there must be understanding on the part of communities about night calls and schools, that we are talking about an intimate relationship, health, of wife, children and husband. If we are to get doctors into rural areas, we will provide a milieu, an environment, which will draw that doctor. We will provide an orientation which will direct him. We will work with the communities and they with us to provide him with the tools to do the job, and then you will get doctors in rural communities just as you get teachers and all the rest. If you try to legislate this problem, you will do nothing but produce continuing difficulty which in turn will have to be legislated, and in the end you will have a legislative strait jacket which, in the last analysis, will harm the consumer much more than it will the physician. Consumers are the ones whose health and lives are in jeopardy. I, as the dean of a medical school, refuse to press young men to go into areas where they will be pawns in the hands of older men. It must be a helpful, cooperative attitude on the part of the older man, and I want to make it clear right here that in ninety-nine instances out of a hundred it probably is; but let us among ourselves be honest and discipline ourselves about that 1 or 2 or 3 per cent and make it clear on the county, state or national level that we will not permit that. I agree with the assistant dean of Western Reserve University that we certainly have our responsibilities for orientation and direction. We will maintain an effort to increase our effect. I will freely admit that we have fallen down in the past perhaps, but I say that we cannot do it alone and that the medical profession on the one hand must encourage, must make it possible for these young men when they come out in the rural areas to function effectively and that lay persons, in addition to that, must recognize that doctors are human beings, that they cannot be moved around even by them like pawns on a chessboard. There is no excess of physicians in Kansas City, Kan. There is no excess of physicians in Wichita. There is no excess of physicians in Topeka—the largest cities. From where I sit, there is a shortage of physicians. In Kansas, we propose to increase our graduating class but without any compromise with medical training standards. If you feel, on the basis of your advice, consultation, wherever it be, in whatever part of the country, that an increased production is needed, then you have a deep obligation to support the medical educator's attempt not to permit standards to be lowered and to fight effectively for increased facilities and the necessary operating budget to run those facilities effectively.

Committee on Nutrition and the Soil

DR. W. L. ALBRECHT, Chairman: That good nutrition goes back to more fertile soil is still a new concept to many. It has not yet engendered fixed opinions and points of view inviting sharp divisions into groups or camps sponsoring one or more kinds of specific group action. The concept is just starting to grow, to be considered, and to be studied. The session of this section was therefore one of educational effort and study more than of resolutions and recommendations for specific action of any group of society.

Good health depends on the state of nutrition more than on anything else. In turn, nutrition depends on the quality of food. Food can, of course, be spoiled in the harvesting, storing, processing, selecting, cooking and serving, but good food can come only from soil supplying all the essential elements and compounds necessary for providing energy and for growth and repair of our bodies.

Plants synthesize the many complex organic and inorganic compounds by which we live. Carbohydrates, for energy service are synthesized on almost any soil. Carbohydrates, proteins, vitamins and all other food essentials are synthesized more completely on the fertile soils delivering essential elements. Provision of proteins is the major food problem, because bulk has become the criterion for agricultural output. A new criterion is needed. Food values as proteins and associated qualities for body building and reproduction rather than bulk delivery are better criteria, but call for more fertile soils.

There is the suggestion that national patterns of human ailments made from records of inductees into the Army might show a relation to the pattern of soil fertility. Declining soil fertility (soil exhaustion) is bringing carbohydrates into prominence, while proteins and other essentials in our food are less common. Conservation of the soil and its fertility are basic to health conservation.

Education concerning the soil as well as our health is needed. Farming is a complexity of many sciences, and education is a requisite for successful farming. Education is needed to help the farmer improve his own health via better nutrition in terms of more fertile soils and better farming of them. We have too long been ignorant of what fertile soils can do.

The farmer, in many instances, is compelled by economics to mine his farm and throw not only the fertility of his soil, but the health of himself and his family, into the bargain for the privilege of being a farmer. He makes no charge for the soil fertility in the goods he sells. According to the concepts controlling income taxes, and those of other taxation procedures, soils cannot be depreciated. Exhausted soils prohibit rural living from offering much attention to health. Under such distorted economics other essentials must be considered first and health last. Poor soils do not invite medical service, just as they do not invite other advantages. Rebuilding the agricultural creative power by rebuilding the soil will rebuild rural health just as better soils brought to the country rural electrification, better sanitation and other advantages through the farmers' own efforts before the days of national rural electrification.

That the subject "Nutrition and the Soil" should find sponsorship by the American Medical Association in a national conference deserves special recognition and commendation, to say nothing of encouragement for future repetition. It represents an approach of positive nature to the health problem and one on a broader base with preventive as well as curative efforts in prospect. Let us hope that through this broader scope more help will be enlisted for better health to more people through education and their own efforts to keep it and to get it through better nutrition by way of better stewardship of our soils.

DISCUSSION

Dr. W. L. Burnap, Fergus Falls, Minn.: I feel that we should not pass by this matter of Dr. Albrecht's without a word because it is of tremendous importance. We know the importance of fertilization. I have been interested in farming a little myself, and I know that it pays to fertilize, but I never got a conception of the fact that one may get a good crop without having the mineral elements there. Dr. Albrecht's reprint should be studied.

Dr. Albrecht: Just a brief remark about the reprint. You might write to the College of Agriculture at the University of Missouri, Columbia, Missouri, for the circular entitled "Our Teeth and Our Soils." It is the reproduction of what I brought yesterday except for the deletion of one or two paragraphs necessary to set it up as a circular.

LUNCHEON MEETING, RURAL HEALTH, FEBRUARY 5

Dr. Crockett, Chairman of the Rural Health Committee of the American Medical Association, introduced the members of the Rural Health Committee to the audience, and then introduced the speakers, after which he expressed thanks to the staff members who had worked on the entire meeting. Dr. Crockett stated that Dr. Sensenich, who was to have appeared on the program, had been called to Washington, D. C., and hence was unable to attend the meeting. He then introduced Dr. Elmer Henderson, Chairman of the Board of Trustees.

Address of Dr. Elmer L. Henderson

Dr. Elmer Henderson, Louisville, Ky.: We are indeed grateful to the Committee on Rural Health for the wonderful work that they have been doing the past few years. We are also grateful for the rural groups that have participated in these meetings. I have attended these meetings the past four years. Every one of them seems a little better than the one before.

I was much impressed by the eleven point resolutions that were passed here yesterday afternoon. They insure, if put into effect, that the rural communities will really have an adequate medical service. I wish to assure you that the officers and members of the Board of Trustees of the American Medical Association support that program 100 per cent.

We are especially anxious to solve the rural problem, and if given time we are going to solve it. We realize your problems. I was raised on a hill farm in Kentucky, and I know a great deal about rural life. We are just as anxious to solve your problems as you are yourself. We know that we can solve them better than any governmental agency regardless of what it is.

It has been my lot for the past few years to travel in a great many countries. I have traveled in practically all the European countries except those back of the iron curtain. I know what any form of governmental medicine is. Whenever politics steps into medicine, medicine begins to deteriorate, and it deteriorates rapidly. That is what we do not want to happen to you—the rural areas or any other areas of the United States.

It was only a short time ago that a man who graduated in medicine did not feel his education complete until he had gone to Europe and spent two or three years. Within the past two years, I have been in Europe four different times. Medical education in Europe is practically nil today, and that is just what will happen to the American people if medical education and medical service are administered under any political organization. That is the reason why we are endeavoring to do everything we can to bring about the proper medical service to all the American people.

It is unfortunate that a great portion of the public cannot understand the doctors' point of view. The majority of the lay people feel that doctors are interested purely from a mercenary standpoint. That is not true. The American Medical Association has been fighting for the great American public. That is what we intend to continue doing.

Address of Dr. W. L. Pressly, M.D., General Practioner of the Year

Dr. W. L. Pressly, Due West, S. C.: May I be permitted, as I begin this talk, to express to the American Medical Association my appreciation of the honor bestowed upon me. I accept it in the spirit of humility, recognizing that it is an honor that has come, not to me personally, but to me as a representative of 130,000 general practitioners. To be the representative, even for a short time, of this company *of splendid men gives one a feeling of great responsibility.* I assure you, it shall be my constant endeavor to use, to the best of my ability, privileges which this honor brings me in furthering the great work of the American Medical Association.

And now I want to express my pleasure in being permitted to be present at this conference. Twice before I have had this privilege and I wish most heartily to congratulate Dr. Crockett on his eminent success in this undertaking. His efforts have made a noteworthy contribution to the solution of the problems of rural health.

During the last decade rural medical care has become the real problem of our profession. It was in recognition of the seriousness of this problem that the officers of the American Medical Association organized the Conference on Rural Health. Personally, I believe that the health and happiness of the rural people is a definite responsibility of the medical profession. We must accept the challenge or suffer the consequences.

When the structure of rural life—I am thinking especially *of the farming people—is jeopardized, the American way* of life is seriously threatened. When a young man is making his choice of a place in which to live and work and rear a family, he will certainly want to know what he may reasonably expect in the way of medical care for himself and his family. The American doctor owes this young man the positive assurance that, whether he chooses the large metropolitan center or the small town or the remote rural district, full medical care will be provided.

The efficiency of our fighting men in the late war, so often remarked upon, can be definitely traced to the fact that they received the very best that medical care could provide. In like manner, our rural areas demand the best in hospital and *medical care if they are to continue to supply the food and* clothing upon which the health and prosperity of our nation depend.

Primarily, this planning and care should be done by the doctors. However, I would not be understood as underestimating the valuable aid by various organizations interested in rural community life and health such as the Grange, Farm Bureau Federations, and similar organizations. During former meetings of this conference, I have been greatly impressed by the constructive thinking and plannig of representatives of such groups. By united effort, not only the problem of *health but* also those of a social, educational and religious nature will receive the attention and emphasis they rightly deserve.

Having been engaged in rural practice for the past thirty-two years, I have witnessed a most gratifying change in rural medical care as regards contagious and infectious diseases. Typhoid, diphtheria, smallpox and malaria have all but been eradicated. Good roads and modern transportation have brought medical care within easy reach of most people. I feel that the Hill-Burton Bill has done much to encourage young men to locate in the smaller towns and rural areas. However, we should not slacken our efforts, for "there remaineth yet very much land to be possessed."

Just here I cannot refrain from saying a few words on my pet theme. No doctor should plan to enter on medical practice alone. It has been my observation that when doctors organize to do group practice they carry forward their work with greatest satisfaction to themselves and greatest benefit to their patients. By this statement, I am not referring to a group of specialists associating themselves together, but to general practitioners seeking to give to their communities the best medical care of which they are capable. Back in *1941, when chairman of the section on general practice* of the Southern Medical Association, I reported that 85 per cent of the patients could be intelligently and skilfully treated by a group working together—the other 15 per cent to be referred for special study to specialists in the fields of surgery, eye, ear, nose, throat, etc. Recent investigations and surveys have revealed that the percentage is even higher than 85 per cent. Much more might be said but time does not permit.

The medical profession must ever keep uppermost the thought that ours is a life of service. It is a service that constantly demands self denial, self sacrifice and hard work. But from this path there can be no turning aside, if we would hold fast the ideal, "Not to be ministered unto, but to minister." In this path the great men of our profession have walked. Today they summon us to face, with courage and devotion, the tasks and problems and opportunities which constitute our high calling.

Doctor Crockett: We have asked Mr. J. O. Christianson, Superintendent of the School of Agriculture of the University of Minnesota and Director of the Agricultural course at that University, to speak.

Address of Mr. J. O. Christianson, Superintendent of the School of Agriculture

MR. J. O. CHRISTIANSON, Minneapolis: Dr. Crockett, I am glad to come from Minnesota to speak of the work being done by the School of Agriculture and Public Health, Blue Cross, Farm Bureau and Blue Shield in the voluntary field. This is not an experiment in a voluntary program. Seventy-five thousand farm people joined together on a voluntary program. It seems to be accepted as a general program.

Sometimes we find that when a group has long been condemned, they rise up and speak for themselves. I want to pay tribute to this great association that gives service to Americans; also service in this rural health conference. Gradually we are educating the public to understand.

I will make a few comments on the reports. Building of hospitals: Local people should build their own facilities. Teachers do not build the public schools. They are built by the community. Build hospitals on that basis and do not quibble as to the cost. There is too much quibbling about definitions while more and more objectives are being forgotten.

Sweden has eight thousand athletic clubs. No wonder Sweden took first place in sports. They have a living program. We are beginning to turn responsibilities over to institutions. It is the duty of the school to train our young people and give them character. Little by little we are abdicating our own responsibility, showing the American kind of democracy that I observed in the countries in Europe. People look more and more to the general practitioner. There is a tendency to turn our problems over to one group and to blame them if things do not turn out satisfactorily. I have indicated the fine state of affairs in the State of Minnesota, where rural health has been given attention through the medical school, the state public health department and farm organizations. We feel in Minnesota that we are making significant progress. Families make connection with doctors before the time of immediate need. It is a program of education. Our extension program in Minnesota is emphasizing this as they will all over the nation. Get people to make contact before it becomes an emergency. That is a problem of education. It takes some time to develop this program. The general philosophy of prepayment health insurance is sound. I do not believe in the paternal philosophy. I think this country grows strong through people's having faith in themselves, in God and in their country. My father and mother came from a foreign land and appreciated the opportunities they had. We lived because of that faith in that country. We grew out of that great home. He felt it was the most important thing of this nature. People are civilized only so far as they can plan ahead. We make provision for the future. The savages lived from day to day. A good test of the social standard of a nation is the interest shown in handling our problems ourselves.

The point of downward turn in past civilizations was when people started to lose faith in themselves and looked for central powers to take care of their problems for them. Modern civilization would be destroyed if the things we take for granted, the rights of individuals, were destroyed. The threat of civilization of the world today is the changing of life values entailed by government doctrines in the medical practice and hospitals. It is the faith in people, it is the mental courage we need to come to again. We must remember it is not so much what belongs to us that determines our destiny, as what we belong to. We must remember that this government cannot be centered in any one person or one place alone. It rests as it should in each person and community. Nothing can take the place of people's belief in themselves and their own organization

CHAIRMAN CROCKETT: I want to take this opportunity in the last two moments of this conference to thank you who have come and contributed of your experience and wisdom to the panel sessions, to those who entered into the program yesterday morning; the Committee on Rural Health of the American Medical Association and the farm resources people who have come to us from the agricultural departments of our agricultural colleges have helped us to make this not a doctor convention, not a lay convention, but a well rounded conference in which we try to have all the elements affecting the problem of rural health represented and represented freely.

Each year these conferences seem to be getting a better response, and as long as that continues, as long as you people show by your attendance and your participation that you think it is worth while, I assure you that we will continue with the program.

Coming Medical Meetings

Alabama, Medical Association of the State of, Montgomery, April 19-21. Dr. Douglas L. Cannon, 519 Dexter Ave., Montgomery 4, Secretary

American Association for the Study of Neoplastic Diseases, Washington, D. C., [illegible] Dr. Eugene R. Whitmore, 2139 Wyoming [illegible] D. C., Secretary.

American Association of Anatomists, Philadelphia, April 13-15. Dr. Normand L. Hoerr, 2109 Adelbert Road, Cleveland 6, Secretary.

American Association of Genito-Urinary Surgeons, White Sulphur Springs, W. Va., Greenbrier Hotel, May 9-11. Dr. Norris J. Heckel, 122 S. Michigan Ave., Chicago 3, Secretary.

American Association of Industrial Physicians and Surgeons, Detroit, Book-Cadillac and Statler Hotels, April 5-9. Dr. Edward C. Holmblad, 28 E. Jackson Blvd., Chicago 4, Managing Director.

American Association of Pathologists and Bacteriologists, Boston, April 15-16. Dr. Howard T. Karsner, 2085 Adelbert Road, Cleveland, Secretary.

American Association of the History of Medicine, Lexington, Ky., May 23-24. Dr. Benjamin Spector, 416 Huntington Ave., Boston 15, Secretary.

American Association on Mental Deficiency, New Orleans, Hotel Roosevelt, April 27-30. Dr. Neil A. Dayton, Box 51, Mansfield Depot, Conn., Secretary.

American Broncho-Esophagological Association, Chicago, Drake Hotel, April 18-19. Dr. Edwin N. Broyles, 1100 N. Charles St., Baltimore 1, Secretary.

American College of Allergists, Chicago, April 14-17. Dr. Fred W. Wittich, 423 LaSalle Medical Bldg., Minneapolis 2, Secretary.

American Dermatological Association, Hot Springs, Va., May 23-26. Dr. Louis A. Brunsting, 102 Second Ave. S.W., Rochester, Minn. Secretary.

American Goiter Association, Madison, Wis., Hotel Loraine, May 26-28. Dr. Thomas C. Davison, 478 Peachtree St., N.E., Atlanta 3, Ga., Secretary.

American Industrial Hygiene Association, Detroit, Book-Cadillac and Statler Hotels, April 5-7. Dr. Henry F. Smyth Jr., 4400 Fifth Ave., Pittsburgh 13, Executive Secretary.

American Laryngological Association, New York, May 16-17. Dr. Louis H. Clerf, 1530 Locust St., Philadelphia, Secretary

American Laryngological, Rhinological and Otological Society, Chicago, Drake Hotel, April 18-20. Dr. C. Stewart Nash, 277 Alexander St., Rochester 7, New York, Secretary.

American Orthopedic Association, Colorado Springs, May 18-21. Dr. C. Leslie Mitchell, Henry Ford Hospital, Detroit 2, Secretary.

American Orthopsychiatric Association, Chicago, Stevens Hotel, April 4-6. Nina Ridenour, Ph.D., 25 W. 54th St., New York 19, Secretary.

American Otological Society, New York, May 18-19. Dr .Gordon D. Hoople, 713 E. Genesee St., Syracuse, N. Y., Secretary.

American Pediatric Society, Atlantic City, May 5-6. Dr. Henry G. Poncher, 1819 W. Polk St., Chicago 12, Secretary.

American Physiological Society, Detroit, April 19-22. Dr. Milton O. Lee, 2101 Constitution Ave., Washington 25, D. C., Executive Secretary

American Psychiatric Association, Montreal, Canada, May 23-27. Dr. Leo H. Bartemeier, General Motors Bldg., Detroit 2, Secretary.

American Society for Clinical Investigation, Atlantic City, May 2. Dr. Paul B. Beeson, Grady Hospital, Atlanta 3, Georgia, Secretary.

American Society for Experimental Pathology, Detroit, April 18-22 Dr. Frieda S. Robscheit-Robbins, 260 Crittenden Blvd., Rochester, N. Y., Secretary.

American Society for Pharmacology and Experimental Therapeutics, Detroit, April 18-22. Dr. Harvey B. Haag, Medical College of Virginia, Richmond 19, Secretary.

American Society for Research in Psychomatic Problems, Atlantic City, Chalfonte-Haddon Hall, April 30-May 1. Dr. Sydney G. Margolis, 714 Madison Ave., New York 24, Executive Secretary.

American Society of Biological Chemists, Detroit, April 17-22. Dr. Otto A. Bessey, 1853 W. Polk St., Chicago 12, Secretary.

American Surgical Association, St. Louis, April 20-22. Dr. Nathan Womack, University of Iowa, Iowa City, Secretary.

American Urological Association, Los Angeles, Hotel Biltmore, May 16-19. Dr. Thomas D. Moore, 899 Madison Ave., Memphis 3, Tenn., Secretary.

Arizona State Medical Association, Tucson, May 8-10. Dr. Frank J. Milloy, 15 E. Monroe St., Phoenix, Secretary.

Arkansas Medical Society, Little Rock, April 14-16. Dr. William R. Brooksher, 602 Garrison Ave., Fort Smith, Secretary.

Association of American Physicians, Atlantic City, May 3-4. Dr. Henry M. Thomas Jr., 1201 N. Calvert St., Baltimore 2, Secretary.

California Medical Association, Los Angeles, May 8-11. Dr. L. Henry Garland, 450 Sutter St., San Francisco 8, Secretary.

Connecticut State Medical Society, New Britain, State Teachers' College, May 3-5. Dr. Creighton Barker, 258 Church St., New Haven, Secretary.

Federation of American Societies for Experimental Biology, Detroit, April 18-22. Dr. Milton O. Lee, 2101 Constitution Ave., Washington 25, D. C., Secretary.

Florida Medical Association, Belleair, April 10-13. Dr. Robert B. McIver, 111 West Adams St., Jacksonville, Secretary.

Georgia, Medical Association of, Savannah, Hotel De Soto, May 10-13. Dr. Edgar D. Shanks, 478 Peachtree St., N.E., Atlanta, Secretary.

Hawaii Territorial Medical Association, Honolulu, May 5-8. Dr. Harry L. Arnold Jr., 510 S. Beretania St., Honolulu, Secretary.

Illinois State Medical Society, Chicago, Palmer House, May 16-18. Dr. Harold M. Camp, 224 S. Main St., Monmouth, Secretary.

Iowa State Medical Society, Des Moines, April 18-21. Dr. Allan B. Phillips, 406 Sixth Ave., Des Moines 9, Secretary.

Kansas Medical Society, Topeka, May 9-12. Dr. D. D. Vermillion, 512 New England Bldg., Topeka, Secretary.

Louisiana State Medical Society, New Orleans, May 5-7. Dr. P. T. Talbot, 1430 Tulane Avenue, New Orleans 13, Secretary.

Maryland, Medical and Chirurgical Faculty of the State of, Baltimore, April 26-27. Dr. George H. Yeager, 1211 Cathedral St., Baltimore 1, Secretary.

Massachusetts Medical Society, Worcester, May 24-27. Dr. H. Quimby Gallupe, 8 Fenway, Boston 15, Secretary.

Medical Library Association, Galveston, Texas, April 10-14. Miss Mildred R. Crowe, Medical College of Alabama Library, Birmingham 5, Ala., Secretary.

Minnesota State Medical Association, St. Paul, Municipal Auditorium, May 9-11. Dr. B. B. Souster, 496 Lowry Medical Arts Bldg., St. Paul 2, Secretary.

Mississippi State Medical Association, Biloxi, May 10-12. Dr.. T. M. Dye, Box 295, Clarksdale, Secretary.

National Tuberculosis Association, Detroit, May 2-6. Dr. H. Stuart Willis, 1790 Broadway, New York 19, Secretary.

Nebraska State Medical Association, Omaha, Hotel Paxton, May 2-5. Dr. R. B. Adams, 416 Federal Securities Building, Lincoln 8, Nebraska, Secretary.

New Jersey, Medical Society of, Atlantic City, Hotel Ambassador, April 25-28. Dr. Earl L. Wood, 315 W. State St., Trenton 8, Secretary.

New Mexico Medical Society, Roswell, May 5-7. Dr. H. L. January, 221 W. Central Ave., Albuquerque, Secretary.

New York, Medical Society of the State of, Buffalo, Hotel Statler, May 2-6. Dr. Walter P. Anderton, 292 Madison Ave., New York 17, Secretary.

North Carolina, Medical Society of the State of, Pinehurst, The Carolina, May 9-11. Dr. Roscoe D. McMillan, P. O. Box 232, Red Springs, Secretary.

North Dakota State Medical Association, Minot, May 14-17. Dr. O. A. Sedlak, 702 First Ave. S., Fargo, Secretary.

Ohio State Medical Association, Columbus, April 19-21. Mr. Charles S. Nelson, 79 E. State St., Columbus 15, Executive Secretary.

Oklahoma State Medical Association, Tulsa, Mayo Hotel, May 15-19. Mr. R. H. Graham, 210 Plaza Court Bldg., Oklahoma City, Secretary.

Rhode Island Medical Society, Providence, May 11-12. Dr. Morgan Cutts, 106 Francis St., Providence 3, Secretary.

Society of American Bacteriologists, Cincinnati, May 15-20. Dr. John Blair, Hospital For Joint Diseases, New York, Secretary.

South Dakota State Medical Association, Yankton, May 22-24. Dr. Roland G. Mayer, 22½ S. Main St., Aberdeen, Secretary.

Southeastern Surgical Congress, Biloxi, Miss., May 23-26. Dr. Benjamin T. Beasley, 45 Edgewood Ave. S.E., Atlanta 3, Ga., Secretary.

Southern Branch, American Public Health Association, Dallas, Texas, Baker Hotel, April 14-16. Dr. George A. Denison, 600 S. Twentieth St., Birmingham, Ala., Secretary.

Southwest Allergy Forum, El Paso, Texas, Hotel Paso del Norte, April 4-5. Dr. O. E. Egbert, First National Bank Bldg., El Paso, Secretary.

Tennessee State Medical Association, Chattanooga, April 12-14. Dr. W. M. Hardy, 706 Church Street, Nashville 3, Secretary.

Texas, State Medical Association of, San Antonio, May 2-5. Dr. Harold Williams, 700 Guadalupe St., Austin, Secretary.

Western Association of Industrial Physicians and Surgeons, Los Angeles, Hotel Biltmore, May 7. Dr. Christopher Leggo, Crockett, Calif., Secretary.

Medical Legislation

STATE LEGISLATION

Delaware

Bill Introduced.—S. 263 proposes the creation of a **State Board of Sterilization.** Three members of the board must be physicians.

Illinois

Bills Introduced.—H. J. R. 19 proposes that the board of trustees of the University of Illinois be urged to take into particular consideration **the rural areas** in which sufficient doctors are not now practicing to maintain the high standard of health to which all of the residents of the state are entitled in considering applications for admission to the College of Medicine of the University of Illinois to the end that a definite preference be shown to the residents of needy areas who express at the time of their application an intention to return to their home communities upon completion of their medical course. H. 246 proposes the creation of a commission to make a thorough study of the laws relative to the care, treatment and training of **feebleminded, mentally ill and epileptic persons** for the purpose of ascertaining needed changes therein.

Indiana

Bill Enacted.—S. 103 has become Chapter 205 of the Laws of 1949. It requires every physician or oculist to report to the state board of health every person diagnosed by him as being **blind or having visual impairment** of a degree sufficient to normally interfere with such person's ability to earn a livelihood.

Iowa

Bills Introduced.—H. 301 proposes the repeal of **the basic science law** and the enactment of provisions which would require the independent examining boards to examine applicants in the basic science subjects in lieu of the previously existing basic science board. H. 530 proposes to amend the **law relating to coroners** so as to require coroners to be licensed practioners of some one of the healing arts. S. J. R. 6 proposes the creation of a special committee to make a comprehensive study of the statutes of the state dealing with **the matter of public health** and the functions of the State Department of Health for the purpose of ascertaining any necessary changes affecting the public health and any advisable changes in the functions, duties and practices of the State Department of Health for the greater protection of the public health in the state.

Kansas
